SEC III NCA A98
1998 ADDENDA SUMMARY OF CHANGES

Page xxvii

Changes given below are identified on the pages by a margin note, **98**, placed next to the affected area.

Page	Location	Change
3	NCA-1100	Title revised
	NCA-1110	(1) Title revised (2) Revised in its entirety
17	NCA-3125	Last sentence of subparagraph (a) corrected by Errata
23	NCA-3370	Title revised
24	NCA-3420	Subparagraphs (c) and (e) corrected by Errata
26	NCA-3520	Subparagraph (o) added by Errata
31	NCA-3841	Subparagraph (f) revised
32	NCA-3842.2	Subparagraph (d) revised
36	NCA-3856.3	Subparagraph (d) revised
52	NCA-5220	Subparagraph (g) corrected by Errata
54, 55	NCA-5290	(1) Title revised (2) Subparagraphs (a), (b), and (c) revised
59	NCA-8120	Subparagraphs (d), (e), and (f) revised
63	NCA-8162	Deleted
	NCA-8163	Redesignated as new NCA-8162
65	NCA-8310	Subparagraph (c) revised
72	NCA-9200	Definition of <i>Modification</i> deleted

NOTE: Volume 42 of the Interpretations to Section III, Divisions 1 and 2, of the ASME Boiler and Pressure Vessel Code follows the last page of this Edition.

IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE ADDENDA DISTRIBUTION SCHEDULE

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

IX Welding and Brazing Qualifications

X Fiber-Reinforced Plastic Pressure Vessels

XI Rules for Inservice Inspection of Nuclear Power Plant Components

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME,

revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that

all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III NCA ACI

THE AMERICAN CONCRETE INSTITUTE

Page xxv

The American Concrete Institute was organized in 1905 to provide industry standards in the field of concrete usage. The organization, which was formed as a result of meetings begun during the Engineering Congress at the Louisiana Purchase Exposition in St. Louis in 1904, was initially entitled the National Association of Cement Users. In 1913, the name of the Society was changed to the American Concrete Institute to better fit the actual scope of its activities and aims, which are to further engineering education, scientific investigation, and scientific research by organizing the efforts of its members for a nonprofit, public service in gathering, correlating, and disseminating information for the improvement of the design, construction, manufacture, use, and maintenance of concrete products and structures.

The day-to-day operation of ACI is administered by an Executive Director, under general supervision of its 18-member Board of Direction, which assigns a part of its administrative duties to standing committees, the ACI Standards Board, and various technical committees.

ACI - TECHNICAL ACTIVITIES COMMITTEE

The Technical Activities Committee, which is appointed by the Board of Direction, is responsible for Institute technical publications, review of standards, the technical program at conventions, and continuing studies of technical committees, from

publications, review of standards, the technical program at conventions, and continuing studies of technical committees, from which arise recommendations for the activities, and the formation or discharge of these groups. TAC members are selected by the ACI Board to represent ACI's varied interests.

ACI - STANDARDS BOARD

The Standards Board, also appointed by the Board of Direction, is responsible for matters of policy, procedure, and appeal pertaining to ACI Standards. All proposed new standards or revisions to existing standards, including minority reports from sponsoring technical committees, are forwarded to the Standards Board through the Technical Activities Committee. On release by the Standards Board, these are published, and after ratification by letter ballot of the ACI membership at large are then available for public use. The primary functions of the Standards Board are to verify that proper standardization procedures have been followed and to rule on matters of policy as related to standards.

ACI - TECHNICAL AND EDUCATIONAL COMMITTEES

Much of the important work of the American Concrete Institute is performed by technical committees that prepare committee reports and standards. Technical committees, composed of volunteer personnel, develop ACI recommendations in their respective fields. Their work, subject to review and approval by the Board of Direction through the Technical Activities Committee and the Standards Board, forms the basis for Institute Standards.

Educational committees, also composed of volunteer personnel, develop seminars, workshops, curriculum guides, and student manuals to further ACI's involvement in education. Their work, subject to review and approval by the ACI Educational Activities Committee, forms the basis for Institute manuals and training programs.

July 1, 1998

American Society Of Mechanical Engineers

SEC III NCA-1000

ARTICLE NCA-1000 SCOPE OF SECTION III

Page 1

[98]

NCA-1100GENERAL

[98]

NCA-1110SCOPE¹

The rules of this Section constitute requirements for the design, construction, stamping, and overpressure protection of:

(a) items (such as vessels, concrete reactor vessels and concrete containments, storage tanks, piping systems, pumps, valves, core support structures, and supports) for use in nuclear power plants²;

(b) spent fuel storage canisters; and

(c) nuclear spent fuel transport containments (see Division 3, Subsection WA).

Section XI contains rules for inservice inspections of items used in nuclear power plants.

[98]

NCA-1120 DEFINITIONS

Definitions of key terms used in Subsection NCA are included in NCA-9000.

¹ Refer to NCA-9000 for definitions of the terms construction, nuclear power plant, and items.

² Specifically excluded from consideration in this Section are tubes or other forms of sheathing used only for cladding nuclear fuel or neutron control material.

NCA-1130 LIMITS OF THESE RULES

(a) The rules of this Section provide requirements for new construction and include consideration of mechanical and thermal stresses due to cyclic operation. They do not cover deterioration which may occur in service as a result of radiation effects, corrosion, erosion, or instability of the material. These effects shall be taken into account with a view to realizing the design or the specified life of the components and supports. The changes in properties of materials subjected to neutron radiation can be checked periodically by means of material surveillance programs. These rules provide requirements for new construction of concrete reactor vessels and containments. They are applicable only to those components that are designed to provide a pressure retaining or containing barrier. They are not applicable to other concrete structures in the plant, as for example to concrete shield and support structures, except as they directly affect the components.

(b) The rules are not intended to be applicable to valve operators, controllers, position indicators, pump impellers, pump drivers, or other accessories and devices, unless they are pressure retaining parts or act as core support structures or supports. If such items are in a support load path, the provisions of NF-1100 apply.

(c) The rules of this Section do not apply to instruments, or permanently sealed fluid filled tubing systems furnished with instruments, but do apply to instrument, control, and sampling piping when specified in Design Specifications.

(d) Auxiliary systems for concrete reactor vessels or containments that are required to assure functional adequacy of the vessels in accordance with the requirements of the Design Specification, including but not limited to concrete cooling systems, thermal insulation, corrosion protection, leakage monitors, and strain monitoring systems, must be delineated fully by appropriate performance, reliability, and test requirements. These rules are not intended to otherwise be applicable to auxiliary systems.

NCA-1140 USE OF CODE EDITIONS, ADDENDA, AND CASES

(a) (1) Under the rules of this Section, the Owner or his designee shall establish the Code Edition and Addenda to be included in the Design Specifications. All items of a nuclear power plant may be constructed to a single Code Edition and Addenda, or each item may be constructed to individually specified Code Editions and Addenda.

Page 4

(2) In no case shall the Code Edition and Addenda dates established in the Design Specifications be earlier than 3 years prior to the date that the nuclear power plant construction permit application is docketed.

(b) Except as permitted in (e) below for materials, Code Editions and Addenda later than those established by (a) above may be used by mutual consent of the Owner or his designee and Certificate Holder. For Division 2 design and construction, the consent of the Designer shall also be obtained. Specific provisions within an Edition or Addenda later than those established in the Design Specifications may be used, provided that all related requirements are met.

(c) Code Cases are permissible and may be used beginning with the date of approval by the ASME Council (and the American Concrete Institute for Division 2 design and construction). Only Code Cases that are specifically identified as being applicable to this Section may be used.

(d) Code Cases may be used by mutual consent of the Owner or his designee, and the Certificate Holder on or after the date permitted by (c) above. For Division 2 design and construction, the consent of the Designer shall also be obtained.

(e) Materials produced and certified in accordance with Code Editions and Addenda other than the one specified for construction of an item may be used, provided all of the following requirements are satisfied.

(1) The material (NCA-1220) meets the applicable requirements of a material specification permitted by paragraph 2121 of the applicable Subsection of the Section III Edition and Addenda specified for construction.

(2) The material meets all the requirements of Article 2000 of the applicable Subsection of the Section III Edition and Addenda specified for construction.

(3) The material was produced under the provisions of a Quality System Program which had been accepted by the Society or qualified by a party other than the Society (NCA-3820), in accordance with the requirements of the latest Section III Edition and Addenda issued at the time the material was produced. Material exempted from portions of the provisions of NCA-3800 by paragraph 2610 of the applicable Subsection of Section III may be used, provided the

requirements of (1) and (2) above are met.

(f) Code Editions, Addenda [including the use of specific provisions of Editions or Addenda permitted by (b) and (e) above], and Cases used shall be reviewed by the Owner or his designee for acceptability to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

NCA-1200 GENERAL REQUIREMENTS FOR ITEMS AND INSTALLATION

NCA-1210 COMPONENTS

Each component of a nuclear power plant shall require a Design Specification (NCA-3250), Design Report (NCA-3350, NCA-3550), and other design documents specified in NCA-3000. Data Reports and stamping shall be as required in NCA-8000.

NCA-1220 MATERIALS

NCA-1221 Metallic Materials

Metallic materials shall be manufactured to an SA, SB, or SFA Specification,³ or any other material specification permitted by this Section. Such material shall be manufactured, identified, and certified in accordance with the requirements of this Section. Tubular products and fittings welded with filler metal require NPT symbol stamping but do not require nameplates.

NCA-1221.1 Metallic Material, ASTM Specification.

Metallic materials produced under an ASTM designation may be accepted as complying with the corresponding ASME Specification, provided the ASME Specification is designated as being identical with the ASTM Specification for the grade, class, or type produced and provided that the material is confirmed as complying with the ASTM Specification by a Certified Material Test Report or Certificate of Compliance from the Material Organization. When a material does not have a corresponding ASME Specification, it may be accepted for Section III, Division 2 construction if it is specified in the Design Documents, provided all materials comply with all of the requirements of CB-2000 for concrete reactor vessels or CC-2000 for concrete containments, as applicable.

NCA-1221.2 Welding Material, AWS Specification.

Welding material produced under an AWS designation may be accepted as complying with the corresponding ASME Specification, provided the latter Specification is indicated to be identical with the AWS Specification and provided the welding material is confirmed as complying with the AWS Specification by a Certified Material Test Report or Certification from the Material Organization.

³ SA or SB Specifications listed under the heading Bars, Rods, Shapes, Forgings may be used as material for any of these product forms even though not all product forms are listed in the SA or SB Specification.

NCA-1222 Nonmetallic Materials - Division 2

NCA-1222.1 Concrete and Grout.

Plastic concrete and grout shall be manufactured to material specifications permitted by this Section. Plastic concrete and grout shall be manufactured and identified in accordance with the requirements of this Section.

NCA-1222.2 Concrete and Grout Constituents.

The constituents of plastic concrete and grout shall be manufactured to material specifications permitted by this Section. Constituents shall be manufactured and identified in accordance with the requirements of this Section.

NCA-1230 PARTS, PIPING SUBASSEMBLIES, AND SUPPORTS

NCA-1231 Parts

The Design Specifications (NCA-3250) and Design Report, Load Capacity Data Sheet, or Design Report Summary (NCA-3350, NCA-3550) for components and supports shall apply to the parts of such components and supports. Data Reports and stamping shall be as required in NCA-8000.

NCA-1232 Piping Subassemblies

The Design Specifications (NCA-3250) and Design Report (NCA-3551.1) for the piping system shall apply to the piping subassemblies of that system. Data Reports and stamping shall be as required in NCA-8000.

NCA-1233 Supports

The Design Conditions for supports shall be included in either the component or piping Design Specifications (NCA-3250) or in a separate Design Specification. A Design Report, Load Capacity Data Sheet, or Design Report Summary (NCA-3551) for each support or group of supports shall be furnished. Data Reports and stamping shall be as required by NCA-8000.

NCA-1260 APPURTENANCES

The design conditions for appurtenances shall be included in either the component Design Specification (NCA-3250) or in a separate Design Specification. A Design Report (NCA-3553) for each appurtenance or group of identical appurtenances for each component shall be furnished, if not included in the component Design Report. The Owner, directly or through his designee, shall be responsible for the overall correlation of the component and appurtenance Design Reports (NCA-3260). Data Reports and stamping shall be as required by NCA-8000.

NCA-1270 MISCELLANEOUS ITEMS

NCA-1271 Control Rod Drive Housings

Control rod drive housings attached to a reactor vessel shall be considered in the Design Specification as a part, appurtenance, or as a separate vessel. The rules of Subsection NB shall apply to those portions of the housings forming a pressure retaining boundary.

NCA-1272 Heater Elements

That portion of heater elements forming a pressure retaining boundary of a nuclear power system shall be considered in the Design Specification either as a part or an appurtenance.

NCA-1273 Fluid Conditioner and Flow Control Devices Other Than Valves

That portion of fluid conditioners or flow control devices, such as filters, demineralizers, traps, strainers, flow nozzles, flow restrictors, venturis, orifice plates [except orifice plates or flow restrictions not exceeding $\frac{1}{2}$ in. (13 mm) nominal thickness which are clamped between flanges], eductors, and similar devices which form the pressure boundary, shall be considered as a piping subassembly, part, appurtenance, component, or material in accordance with the rules of this Section.

NCA-1274 Penetration Assemblies

Penetration assemblies shall be considered in the Design Specification to be either parts or appurtenances.

NCA-1275 Rupture Disk Devices

The portion of the rupture disk holder which forms the pressure boundary shall be considered as material, a part, or an appurtenance. The rupture disks are not required to be Code material.

NCA-1280 INSTALLATION

NCA-1281 Activities and Requirements

The requirements pertaining to installation governing materials, fabrication, examination, testing, inspection,

Page 6

stamping, and reporting shall be in accordance with the rules applicable to the classification and type of component involved. When joining components of different classifications, the more restrictive requirements shall govern, except that connections between piping and other components shall be considered part of the piping. Data Reports and stamping shall be as required in NCA-8000.

NCA-1282 Support Installation

Installation of supports consists of those activities required to attach supports to the building structure and join parts and materials by welding or mechanical means. The requirements pertaining to installation governing materials, fabrication, examination, inspection, stamping, and reporting shall be in accordance with the rules applicable to the classification and type of support involved.

NCA-1283 Services

Services such as handling, rigging, setting, and temporary bolting and temporary aligning may be performed by organizations who are non-Certificate Holders as provided for in NCA-3125.

July 1, 1998

American Society Of Mechanical Engineers

SEC III NCA-2000

ARTICLE NCA-2000 CLASSIFICATION OF COMPONENTS AND SUPPORTS

Page 7

NCA-2100 GENERAL REQUIREMENTS

NCA-2110 SCOPE

(a) Division 1 specifies rules for:

- (1) nuclear power system metal components, parts, and appurtenances
- (2) metal containment vessels
- (3) supports

(b) Division 2 specifies rules for:

- (1) concrete reactor vessels
- (2) concrete containments

(c) While providing for several classes of construction (NCA-2120, NCA-2130), this Section does not provide guidance in the selection of a specific classification to fit a component in a given system. Such guidance is derived from systems safety criteria for specific types of nuclear power systems, such as pressurized water reactors, boiling water reactors, or high temperature gas cooled reactors, and may be found in engineering standards or in the requirements of regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

(d) The Owner of a nuclear power plant shall be responsible for applying system safety criteria to classify the equipment in the nuclear power plant to be constructed in accordance with the rules of this Section (NCA-2120 and NCA-2130). Classification shall be included in the Design Specification.

NCA-2120 PURPOSE OF CLASSIFYING ITEMS OF A NUCLEAR POWER PLANT

Construction rules are specified for items which are designated Code Classes 1, 2, 3, CS, MC, CB, and CC. These Code classes are intended to be applied to the classification of items of a nuclear power system and containment system. Within these systems the Code recognizes the different levels of importance associated with the function of each item as related to the safe operation of the nuclear power plant. The Code classes allow a choice of rules that provide assurance of structural integrity and quality commensurate with the relative importance assigned to the individual items of the nuclear power plant.

NCA-2130 CLASSIFICATIONS AND RULES OF THIS SECTION

NCA-2131 Code Classes and Rules of Division 1

(a) Division 1 provides rules for the construction of items in the following Code classes:

Class 1 - items constructed in accordance with the rules of Subsection NB

Class 2 - items constructed in accordance with the rules of Subsection NC

Class 3 - items constructed in accordance with the rules of Subsection ND

Class MC - metal containment vessels constructed in accordance with the rules of Subsection NE

Class CS - core support structures constructed in accordance with the rules of Subsection NG

(b) Division 1 also provides rules for:

(1) supports constructed in accordance with the rules of Subsection NF

(2) internal structures constructed in accordance with the rules of Subsection NG

NCA-2132 Rules of Division 2

Division 2 of this Section provides rules for:

(a) concrete reactor vessels designed and constructed in accordance with the rules of Subsection CB; and

(b) concrete containments designed and constructed in accordance with the rules of Subsection CC.

NCA-2133 Multiple Code Class Components

(a) Compartments in components consisting of multiple compartments such as heat exchangers may be

Page 10

assigned different Code classes, provided any interactions between compartments produced by service conditions are taken into account and these conditions are specified in the Design Specifications.

(b) Supports for multiple Code class components shall be constructed in accordance with the rules of Subsection NF for the more restrictive class.

NCA-2134 Optional Use of Code Classes

(a) Items classified as Class 2 in their Design Specifications may be constructed and stamped in accordance with the rules of Subsection NB.

(b) Items classified as Class 3 in their Design Specifications may be constructed and stamped in accordance with the rules of Subsection NB or NC.

(c) Containment vessels classified as Class MC in their Design Specification may be constructed and stamped in accordance with the rules of Subsection NB, provided the rules of NE-7000 are applied in lieu of the rules of NB-7000 for protection against overpressure.

(d) When an item is optionally classified to a higher class, the Design Specifications shall identify the minimum required class as well as the optionally selected higher class.

(e) Those items designated as parts (Division 1) or appurtenances (Division 1) when used in a Division 2 component, if stamped as parts (Division 1), may be used without further stamping under Division 2 requirements, provided:

(1) the Designer identifies the parts to be stamped under Division 1 requirements in the Construction Specification;

(2) the Designer separately establishes that the use of such parts satisfies the requirements of the Design Specification, the Construction Specifications, and the Design Drawings.

NCA-2135 Code Cases for Division 2 Parts

Parts specified to meet the requirements of Division 1 for material, design, fabrication, and examination may be stamped CB or CC in accordance with Division 2 when used in a Division 2 component (CB-1000, CC-1000). For these parts, Division 1 Code Cases which are applicable for material, design, fabrication, and examination may be used for Division 2 construction in accordance with NCA-1140.

NCA-2140 DESIGN BASIS

NCA-2141 Consideration of Plant and System Operating and Test Conditions¹

(a) Components and supports of a nuclear power system (NCA-1110) may be subjected to plant and system operating and test conditions which are required to be considered in the design and overpressure protection of the components and the design of supports in order to satisfy applicable systems safety criteria. The significance of plant and system operating and test conditions upon design may vary from item to item within a system for a specific operating or test condition experienced by the plant or system. The temperatures, pressures, and mechanical loads to which components and supports are subjected in consequence of plant or system operating and test conditions are referred to in this Section as component or support Design, Service, or Test Loadings.

(b) The definition of plant and system operating and test conditions, and the determination of their significance to the design and operability of components and supports of a nuclear power system, are beyond the scope of this Section. Appropriate guidance for the selection of plant or system operating and test conditions, which may be determined to be of significance in the selection of component or support Design, Service, or Test Loadings, the combinations thereof, and the corresponding acceptable Limits, may be derived from systems safety criteria documents for specific types of nuclear power systems and may be found in the requirements of regulatory and enforcement authorities having jurisdiction at the site.

NCA-2142 Establishment of Design, Service, and Test Loadings and Limits

In the Design Specification, the Owner or his designee shall identify the loadings and combinations of loadings and establish the appropriate Design, Service, and Test Limits for each component or support.

¹ Plant and system operating conditions are commonly referred to as normal, upset, emergency, and faulted.

(a) *Loadings.* The Design, Service, and Test Loadings shall be identified considering all plant or system operating and test conditions anticipated or postulated to occur during the intended service life of the component or support. Service Loadings are not required to be identified for Class 2 and 3 components, Class 2 and 3 component supports, and Class MC supports, when the Design Pressure and Design Mechanical Loads result in stresses of greater magnitude, relative to

Page 11

the allowable stress or stress intensity at the Design Temperature, than would the Service Loadings relative to the allowables for the appropriate Service Level. When this is not the case, and for piping and its supports, Service Loadings shall be identified in the Design Specification. For the Class MC containment vessel, loadings associated with the containment function shall be identified as Design Loadings, except as provided in NE-3000.

(b) *Limits.* The selection of Design, Service, and Test Limits for each item shall be established in accordance with NCA-2142.4. The rules of this Section do not assure operability of components in which mechanical motion is required. The selection of limits for Design, Service, or Test Loadings to assure operability is beyond the scope of this Section.

However, the rules of this Section do require operability of pressure relief valves. When assurance of operability is required, it is the responsibility of the Owner to define the appropriate limiting parameters by referring to documents which specify the requirements for operability. Such parameters are outside the scope of this Section [NCA-1130, NCA-2160, and NCA-5210(b)].

NCA-2142.1 Design Loadings.

Design Loadings for components and supports shall be in accordance with (a), (b), and (c) below and the additional requirements of the applicable Subsections of this Section.

(a) *Design Pressure.* The specified internal and external Design Pressure shall not be less than the maximum difference in pressure between the inside and outside of the item, or between any two chambers of a combination unit, which exists under the most severe loadings for which the Level A Service Limits are applicable. The Design Pressure shall include allowances for pressure surges, control system error, and system configuration effects such as static pressure heads.

(b) *Design Temperature.* The specified Design Temperature shall not be less than the expected maximum mean metal temperature through the thickness of the part considered for which Level A Service Limits are specified. Where a component is heated by trace heating, such as induction coils, jacketing, or by internal heat generation, the effect of such heat input shall be considered in establishing the Design Temperature. The Design Temperature shall consider control system error and system configuration effects.

(c) *Design Mechanical Loads.* The specified Design Mechanical Loads shall be selected so that when combined with the effects of Design Pressure, they produce the highest primary stresses of any coincident combination of loadings for which Level A Service Limits are designated in the Design Specification.

NCA-2142.2 Service Loadings.

When the Design Specification or applicable Subsection of this Section requires computations to demonstrate compliance with specified Service Limits, the Design Specification shall provide information from which Service Loadings can be identified (pressure, temperature, mechanical loads, cycles, or transients). The Design Specification shall designate the appropriate Service Limit (NCA-2142.4) to be associated with each Service Loading or combination of Loadings.

NCA-2142.3 Test Loadings

(a) Test Loadings include pressure tests required by this Section.

(b) Loads due to other types of tests as may be required by the Owner shall be included in the Design Specification.

NCA-2142.4 Design, Service, and Test Limits

(a) *Design Limits.* The limits for Design Loadings shall meet the requirements of the appropriate Subsection of this Section.

(b) *Service Limits.* The Design Specification may designate Service Limits as defined in (1) through (4) below.

(1) *Level A Service Limits.* Level A Service Limits are those sets of limits which must be satisfied for all Level A Service loadings identified in the Design Specifications to which the component or support may be subjected in the performance of its specified service function.

(2) *Level B Service Limits.* Level B Service Limits are those sets of limits which must be satisfied for all Level B Service loadings identified in the Design Specifications for which these Service Limits are designated. The component or support must withstand these loadings without damage requiring repair.

(3) *Level C Service Limits.* Level C Service Limits are those sets of limits which must be satisfied for all Level C Service loadings identified in the Design Specifications for which these Service Limits are designated. These sets of limits permit large deformations in areas of structural discontinuity which may necessitate the removal of the component or support from service for inspection or repair of damage to the component or support. Therefore, the selection of this limit shall be reviewed by the Owner for compatibility with established system safety criteria (

NCA-2141).

(4) *Level D Service Limits.* Level D Service Limits are those sets of limits which must be satisfied for all Level D Service loadings identified in the Design Specifications for which these Service Limits are designated. These sets of limits permit gross general deformations with some consequent loss of dimensional stability

Page 12

and damage requiring repair, which may require removal of the component or support from service. Therefore the selection of this limit shall be reviewed by the Owner for compatibility with established system safety criteria (NCA-2141).

(c) *Alternative Service Limits.* Components or supports may be alternatively designed using more restrictive Service Limits than specified in the Design Specification. For example, Level B Service Limits may be used where Level C Service Limits have been specified.

(d) *Test Limits*

(1) The limits for Test Loadings shall meet the requirements of the appropriate Subsection of this Section.

(2) The selection of Limits for other tests defined by the Owner [NCA-2142.3(b)] shall be included in the Design Specification.

NCA-2143 Acceptance Criteria

(a) Components and supports shall comply with the design rules established for Design, Service, and Test Loadings in the appropriate Subsections.

(b) It is the responsibility of the Owner to define acceptance criteria for the Service Level Loading for which acceptance criteria are not contained in this Section.

(c) Design documentation shall be completed in accordance with the requirements of the Subsection applicable to the component or support.

NCA-2144 Concrete Reactor Vessels and Concrete Containments

NCA-2144.1 Concrete Reactor Vessels.

Concrete reactor vessels, in addition to satisfying the structure design allowables (CB-3400), shall be evaluated for load categories in CB-3220.

NCA-2144.2 Concrete Containments.

Concrete containments, in addition to satisfying the structure design allowables (CC-3400), shall be evaluated for load categories in CC-3200.

NCA-2160 SPECIAL REQUIREMENTS APPLIED TO CODE CLASSES

Contractual arrangements between the Owner and Certificate Holder which specify requirements in addition to or more restrictive than those specified by the rules of this Section for the applicable class of an item may be applied, provided such requirements do not negate any rules of this Section. Such special contractual requirements are beyond the scope of this Section and shall not apply as conditional requirements for Code construction of items.

American Society Of Mechanical Engineers

SEC III NCA-3000

ARTICLE NCA-3000 RESPONSIBILITIES AND DUTIES

Page 13

NCA-3100 GENERAL

NCA-3110 RESPONSIBILITIES VS. LEGAL LIABILITIES

The various parties involved in the construction of a nuclear power plant or items which come under the jurisdiction of this Section have specific responsibilities for complying with these requirements. The responsibilities set forth herein relate only to Code compliance and are not to be construed as involving contractual or legal liabilities.

NCA-3120 ACCREDITATION

NCA-3121 Types of Certificates

Table NCA-8100-1 lists the types of certificates issued by the Society and indicates the responsibilities assumed by each Certificate Holder. Further details of these responsibilities are contained in this Article.

[98]

NCA-3125 Subcontracted Services

(a) Services may be subcontracted which are both within and beyond the scope of this Section. There are no requirements for the subcontracting of services beyond the scope of this Section. Services covered by this Section may either be of a type for which the Society issues Certificates, or may be of the type for which the Society does not issue a Certificate. Subcontracts for activities for which Certificates are required shall be made only to Certificate Holders. A Certificate Holder may subcontract to another organization the surveying and auditing of his subcontractors and Material Organizations, but must retain the responsibility for these activities and for the qualification of these subcontractors and Material Organizations.

(b) It is the right of an N Certificate Holder to subcontract stress analysis or complete design of all or a portion of a component. However, the N Certificate Holder is responsible for the design of the component and for the Design Output Documents.

(c) The Quality Assurance Manual shall describe the manner in which the Certificate Holder controls and accepts the responsibility for the subcontracted activities.

[98]

NCA-3130 WELDING¹ AND SUBCONTRACTING DURING CONSTRUCTION

NCA-3131 Welding During Construction

For Divisions 1 and 2, it is required that all shop and field welding during Code construction be done only by a Certificate Holder holding a certificate appropriate to the scope of welding to be performed. A Certificate Holder may engage individuals by contract for their services as welders or welding operators at the site location shown on the Certificate, provided conditions of (a) through (g) below are met. This is an acceptable method of complying with Section IX requirements concerning responsibility for welding.

(a) The work to be done by such welders and welding operators is within the scope of the Certificate.

(b) The use of such welders and welding operators is contained in the Quality Assurance Program of the Certificate Holder. The Quality Assurance Program (NCA-3462, NCA-3562, NCA-3662, or NCA-3762) shall include a requirement for direct supervision and direct technical control of the welders and welding operators by the Certificate Holder during such welding operations, and this program shall be acceptable to the Certificate Holder's Authorized Inspection Agency (NCA-5121) performing the inspections.

(c) The welding procedures have been properly qualified by the Certificate Holder, and Code responsibility for such procedures is retained by the Certificate Holder.

- (d) The welders and welding operators are qualified by the Certificate Holder to perform such procedures.
- (e) The Certificate Holder shall have contractual control of the welding operation, including authority to assign or remove welders and welding operators at his discretion.
- (f) The Certificate Holder shall be responsible for Code compliance of the completed item or installation including Code Symbol stamping and providing the completed appropriate Data Report Form.
- (g) Exceptions to the requirements of this paragraph for furnace brazing operations are specified in NCA-3561(c), NCA-3661(b), and NCA-3761(b).

NCA-3132 Subcontracted Construction Services - Division 2

A Certificate Holder may engage individuals or organizations not holding a Certificate to provide subcontracted construction services other than welding at the site location shown on the Certificate, provided all of the following conditions are met.

- (a) The activities, such as placement of concrete or reinforcing steel, to be performed by subcontracted individuals or organizations are included within the Scope of the Certificate of the Certificate Holder, and a description of the subcontracted activities is contained in the Certificate Holder's Quality Assurance Program.
- (b) The Quality Assurance Program (NCA-3462, NCA-3662) shall include requirements for direct technical control of such individuals or organizations. Technical control by the Certificate Holder includes controlling the performance of all Code required examinations, inspections, and tests including documentation and record retention. The Quality Assurance Program shall be acceptable to the Society (NCA-8120) and to the Authorized Nuclear Inspector Supervisor (NCA-5122).
- (c) The construction procedures have been approved by the Certificate Holder, and Code responsibility for such procedures is retained by the Certificate Holder.
- (d) Splicers for sleeve filler metal splices or mechanical reinforcing bar splices are qualified as required by this Section, provided their qualifications are reviewed and approved by the Certificate Holder.
- (e) The Certificate Holder shall have contractual control of the construction operation, including authority to assign or remove individuals or organizations at his discretion.
- (f) The Certificate Holder shall be responsible for Code compliance of the completed item including Code Symbol stamping and providing the completed, applicable Data Report Form.
- (g) Provisions shall be made by the Certificate Holder for the Authorized Inspector to have access to all areas and functions required to perform his duties, including those of procedure development and qualification performed by a subcontractor for the Certificate Holder.

NCA-3200 OWNER'S RESPONSIBILITIES

NCA-3220 CATEGORIES OF THE OWNER'S RESPONSIBILITIES

The responsibilities of the Owner include the requirements of (a) through (u) below:

- (a) obtaining an Owner's Certificate (NCA-3230);
- (b) documenting a Quality Assurance Program (NCA-8140);
- (c) obtaining a written agreement with an Authorized Inspection Agency (NCA-3230 and NCA-8130);
- (d) certifying and filing of Owner's Data Report (NCA-3280);
- (e) establishing the Code Editions, Addenda, and Code Cases to be used in Design Specifications, and determining that they are acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site (NCA-1140)

NCA-1140);

(f) verifying through a review of the required documentation that the Code Editions, Addenda, and Code Cases used for completed components and supports, and materials satisfy NCA-1140 and are acceptable to the regulatory and enforcement authorities;

(g) classifying equipment (NCA-2110 and NCA-3253);

(h) designating the Designer, Constructor, and Fabricators for Division 2 construction and verifying through a review of the required documentation that the Designer has fulfilled his responsibilities for Division 2 construction;

(i) providing adequate structures, foundations, and auxiliary systems for the items covered by both Divisions of this Section (NCA-3240);

(j) providing and correlating Design Specifications, including establishment of component and system boundaries (NCA-3252);

(k) certifying Design Specifications (NCA-3255);

(l) reviewing Design Reports (NCA-3260);

(m) designating the overpressure protection requirements for each component or system, including the Class of overpressure protection rules assigned to each component or system and the location of the overpressure protection devices;²

² As explained in NB-, NC-, ND-, and NE-7000, an overpressure protection device or devices may be provided to protect one or more components, portions of the nuclear power system, or portions of components, provided they are so designed and located so that the overpressure protection requirements of all protected components and systems are fully complied with and that the safety relieving devices cannot be isolated from any component or system protected by them while the component or system is operating.

(2) Information provided to the indicated participants when required to satisfy their designated responsibilities under this Section. Other information provided only by specific arrangement with the Owner. Participants are required to furnish only such information as is necessary to permit the recipient to perform his duties in conformance with this Section. Other information may be furnished at the discretion of the responsible parties.

TABLE NCA-3200-1 DOCUMENT DISTRIBUTION FOR DIVISION 2 CONSTRUCTION¹

- (n) providing and filing the Overpressure Protection Report (NCA-3270) required for the nuclear power system;
- (o) reviewing and approving the Construction Specification, Design Drawings, and Construction Report for Division 2 construction (Table NCA-3200-1);
- (p) making available to the Inspector the documents specified by this Section and those requested by the Inspector to ensure compliance with Code requirements (NCA-5242);
- (q) designating Designer's responsibilities with respect to construction surveillance for Division 2 construction (NCA-3252);
- (r) providing for the design and arrangement of components to permit accessibility in accordance with Section XI;
- (s) designating the preservice inspection requirements [NCA-3252(c)];
- (t) designating records to be maintained and providing for their maintenance (NCA-3290);
- (u) performing other duties as defined throughout this Section.

The activities necessary to provide compliance with responsibilities assigned to the Owner by (e) through (u) above may be performed on the Owner's behalf by a designee; however, the responsibility for compliance remains with the Owner.

NCA-3230 OWNER'S CERTIFICATE

The Owner, after receipt of notification from the regulatory authority that an application for a Construction Permit for a specific plant has been docketed, shall obtain an Owner's Certificate from the Society for unit(s) docketed concurrently for each site prior to beginning field installation. The information to be supplied by the Owner when making applications is given in forms issued by the Society. A written agreement with an Authorized Inspection Agency (NCA-8130) is required prior to application.

Page 20

NCA-3240 PROVISION OF ADEQUATE SUPPORTING STRUCTURES

It is the responsibility of the Owner to assure that intervening elements, foundations, and building structures adequate to support the items covered by this Section are provided and to assure that jurisdictional boundary interfaces for Code items are defined and compatible. Loads imposed upon structures outside the scope of this Section by items covered by this Section shall be defined in the Design Specification. Concrete reactor vessels or concrete containments bearing on soil or rock or on caissons or piles require an allowable bearing pressure or allowable load per caisson or pile to be determined by the Owner and furnished to the Designer.

NCA-3250 PROVISION OF DESIGN SPECIFICATIONS

NCA-3251 Provision and Correlation

It is the responsibility of the Owner to provide, or cause to be provided, Design Specifications for components, supports, and appurtenances. The Owner, either directly or through his designee, shall be responsible for the proper correlation of all Design Specifications. Separate Design Specifications are not required for parts, piping subassemblies, appurtenances, or supports when they are included in the Design Specification for a component (NCA-1210). However, the applicable data from the component Design Specification (Division 1) or the Construction Specification and Design Drawings (Division 2) shall be provided in sufficient documented detail to form the basis for fabrication in accordance with this Section.

NCA-3252 Contents of Design Specifications³

(a) The Design Specifications shall contain sufficient detail to provide a complete basis for Division 1 construction or Division 2 design in accordance with this Section. Such requirements shall not result in construction which fails to conform with the rules of this Section. All Design Specifications shall include (1) through (7) below:

(1) the functions and boundaries of the items covered (NCA-3254);

3 See Appendix B, except that for core support structures see Appendix J.

(2) the design requirements [NCA-2110(a) and (b) and NCA-2140] including all required overpressure protection requirements [NCA-3220(m)];

(3) the environmental conditions, including radiation;

(4) the Code classification of the items covered (NCA-2000);

(5) material requirements including impact test requirements;

(6) when operability of a component is a requirement, the Design Specification shall make reference to other appropriate documents which specify the operating requirements;

(7) the effective Code Edition, Addenda, and Code Cases to be used for construction.

(b) A Design Specification shall be provided for each concrete reactor vessel or concrete containment serving in a single power generating unit or for multiple concrete reactor vessels or concrete containments at the same site. In addition to the requirements of (a) above, the Design Specifications for Division 2 items shall also include (1) through (7) below:

(1) design life;

(2) corrosion effects;

(3) structural acceptance testing requirements (CB-6000 and CC-6000);

(4) shielding requirements;

(5) construction surveillance required by the Designer;

(6) foundation type and allowable loading, if applicable (NCA-3240);

(7) loads from internal structures (NCA-2132).

(c) The Design Specification shall identify those components and/or parts that require a preservice examination and shall include the following:

(1) Examination

(a) Edition and Addenda of Section XI to be used;

(b) category and method; and

(c) qualifications of personnel, procedures, and equipment.

(2) Welds

(a) surface conditioning requirements; and

(b) identification/markings system to be used.

NCA-3253 Classification of Components, Parts, and Appurtenances

The Owner, either directly or through his designee, shall establish the Code classification of the items which comprise the nuclear power plant.

Page 21

NCA-3254 Boundaries of Jurisdiction

In order to define the boundaries of components with respect to adjacent components, intervening elements, and other structures, the Design Specifications shall include:

(a)

- (a) the locations of each such boundary;
- (b) the forces, moments, strains, or displacements which are imposed at each such boundary;
- (c) the structural characteristics of the attached components or structures, whether or not they are within this Section's jurisdiction when such components or structures provide constraints to the movement of components or appurtenances;
- (d) when the foundation support is constructed as an integral part of the concrete reactor vessel or concrete containment, it shall be included within this Section's Division 2 jurisdiction to the extent required by NCA-2132.

NCA-3254.1 Definition of Division 1 Boundaries

- (a) The boundaries for Class 1 components are given in NB-1130.
- (b) The boundaries for Class 2 components are given in NC-1130.
- (c) The boundaries for Class 3 components are given in ND-1130.
- (d) The boundaries for Metal Containment Vessels are given in NE-1132.
- (e) The boundaries for Supports are given in NF-1130.
- (f) The boundaries for Core Support Structures are given in NG-1130.

NCA-3254.2 Definition of Division 2 Boundaries.

The Design Specification shall define the boundaries of Division 2 in accordance with the limits defined in NCA-1120; it shall also show the external boundaries of the component with respect to its supporting structures. Where the support is constructed as an integral part of the concrete vessel or the concrete containment, it shall be included within the jurisdiction of Division 2 to the extent required by NCA-1120. The Design Specification shall include the specific dimensional location of each boundary, including the boundaries for parts and appurtenances designated to meet the requirements of Division 1.

NCA-3255 Certification of the Design Specifications

The Design Specifications shall be certified to be correct and complete and to be in compliance with the requirements of NCA-3250 by one or more Registered Professional Engineers, competent in the applicable field of design and related nuclear power plant requirements and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices. These Registered Professional Engineers are not required to be independent of the organization preparing the Design Specifications. Document distribution for Division 2 construction is shown in Table NCA-3200-1.

NCA-3256 Filing of Design Specifications

(a) The Design Specifications in their entirety shall become a principal document governing design and construction of items. A copy of the Design Specification shall be made available to the Inspector at the manufacturing site before fabrication begins, and a copy shall be filed at the location of the installation and made available to the enforcement authorities having jurisdiction over the plant installation before components or appurtenances are placed in service. In the case of parts, piping subassemblies, appurtenances, and supports, the Design Specifications need not be made available to the Inspector at the fabrication site (NCA-3251). However, the applicable data from the Design Specifications which form the basis for fabrication shall be made available to the Inspector at the fabrication site. Document distribution for Division 2 construction is shown in Table NCA-3200-1.

(b) For pumps and valves 4 in. nominal pipe size (DN 100) and less, for linear supports used as mechanical snubbers, and for standard supports, the Certificate Holder may provide his own Design Specification in accordance with NCA-3252 as a basis for construction. Prior to installation, the Owner or his designee shall be responsible for reconciling the Certificate Holder's Design Specification with his own Design Specification.

NCA-3260 REVIEW OF DESIGN REPORT

- (a) The Design Report which the Certificate Holder or the Designer provides shall be reviewed by the Owner or his

designee to determine that all the Design and Service Loadings as stated in the Design Specification have been evaluated, and that the acceptance criteria explicitly provided for in this Section, or additional acceptance criteria permitted by this Section when established in the Design Specification, associated with the specified Design and Service Conditions, have been considered. The responsibility for the method of analysis and the accuracy of the Design Report remains with the Certificate Holder or the Designer.

Page 22

(b) Except as provided for in NCA-3260(c) below, documentation shall be provided by the Owner or his designee to indicate that the review required by NCA-3260(a) above has been conducted. Prior to the stamping of the component, a copy of this documentation shall be attached to the copy of the Design Report which is made available to the Inspector. A copy of this documentation shall be included with the Design Report, which is filed at the location of the installation in accordance with NCA-4134.17 and made available to the regulatory and enforcement authorities having jurisdiction at the site of the nuclear power plant installation. Document distribution for Division 2 construction is shown in Table NCA-3200-1.

(c) When a Certified Design Report Summary (NCA-3551.3) is furnished in lieu of a Design Report (NCA-3551.1), for standard supports, documentation shall be provided by the Owner or the Owner's designee to indicate that the Certified Design Report Summary has been reviewed in accordance with NCA-3260(a) above. Prior to stamping of the component, including piping systems, a copy of this documentation shall be attached to the Certified Design Report Summary which is made available to the Inspector. A copy of this documentation and the Certified Design Report Summary shall be filed at the location of the installation in accordance with NCA-4134.17 and made available to the regulatory and enforcement authorities having jurisdiction at the site of the nuclear power plant.

NCA-3270 OVERPRESSURE PROTECTION REPORT

NCA-3271 Responsibility and Content

It is the responsibility of the Owner to provide, or cause to be provided, an Overpressure Protection Report for each component or system (NB-7200, NC-7200, ND-7200, NE-7200, or CB-7200).

NCA-3272 Certification of Report

The Report shall be certified as specified in NB-7230, NC-7230, ND-7230, NE-7230, or CB-7230.

NCA-3273 Filing of Report

The Report shall be filed as specified in NB-7250, NC-7250, ND-7250, NE-7250, or CB-7240.

NCA-3280 OWNER'S DATA REPORT AND FILING

The Owner or his designee shall prepare the Form N-3 (Appendix V).

NCA-3290 OWNER'S RESPONSIBILITY FOR RECORDS

The Owner shall be responsible for designating the records to be maintained (NCA-4134.17). The Owner shall also be responsible for continued maintenance of the records required by this Section and Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components, at the power plant site, the Certificate Holder's plant, or other locations determined by the Owner. The Owner shall advise the Enforcement Authority in writing regarding the location of the records.

NCA-3300 RESPONSIBILITIES OF A DESIGNER - DIVISION 2

NCA-3320 CATEGORIES OF THE DESIGNER'S RESPONSIBILITY

The Designer has the following categories of responsibility:

(a) prepare structural design of the component in conformance with this Section and the Design Specification (NCA-3250);

- (b) prepare the Design Drawings and Construction Specification (NCA-3340);
 - (c) prepare and submit the Design Report (NCA-3350);
 - (d) surveillance of construction to the extent designated by the Owner in the Design Specification (NCA-3220);
 - (e) review of construction documents (NCA-3450) as specified in the Construction Specification;
 - (f) establish and maintain a Quality Assurance Program (NCA-4134);
 - (g) modifications of Design Drawings and Construction Specification (NCA-3370);
 - (h) certification of the Construction Report (NCA-3380);
 - (i) document distribution as shown in Table NCA-3200-1.
-

NCA-3340 DESIGN DRAWINGS AND CONSTRUCTION SPECIFICATION

NCA-3341 Design Drawings

The Design Drawings shall contain the following:

- (a) concrete and steel liner thickness;
- (b) size and location of reinforcing steel;
- (c) size and location of prestressing tendons;
- (d) size and location of penetrations;
- (e) all other details necessary to construct the item in accordance with the requirements of the Design Specification, the Construction Specification, and this Section.

NCA-3342 Construction Specification

The Construction Specification shall contain the following:

- (a) material specifications;
- (b) material shipping, handling, and storage requirements;
- (c) inspection requirements;
- (d) appropriate Code references;
- (e) requirements for personnel or equipment qualification;
- (f) material or part examination and testing requirements;
- (g) acceptance testing requirements;
- (h) leak testing requirements;
- (i) requirements for shop drawings;
- (j) requirements for batching, mixing, placing, and curing concrete;
- (k) requirements for the fabrication and installation of the prestressing system, reinforcing steel, embedments, and all other parts;
- (l) identification of parts requiring a Code stamp;
- (m) design life for parts and materials where necessary to establish compliance with the Design Specification;
- (n) construction surveillance to be performed by the Designer as required by the Design Specification;

(o) construction documents which require review by the Designer and those which require both review and approval by the Designer - as a minimum, these will include the requirements of Table NCA-3200-1.

NCA-3350 DESIGN REPORT

The Designer shall prepare a Design Report in sufficient detail to show that the applicable stress limitations are satisfied when the component is subject to the loading conditions specified in the Design Specification and this Section. The Design Report prepared by the Designer shall contain calculations and sketches substantiating that the design is in accordance with the Design Specification and this Section. Distribution of the Design Report is shown in Table NCA-3200-1.

NCA-3360 CERTIFICATION OF THE CONSTRUCTION SPECIFICATION, DESIGN DRAWINGS, AND DESIGN REPORT

(a) The Construction Specification, Design Drawings, and Design Report shall be reviewed and certified to be correct and in accordance with the Design Specification and this Section by one or more Registered Professional Engineers competent in the field of design of concrete components and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices. These Registered Professional Engineers are not required to be independent of the organization designing the component. Distribution of Construction Specification, Design Drawings, and the Design Report is shown in Table NCA-3200-1.

(b) In order for the Designer to certify the Construction Specification and Design Drawings, it is necessary that the Design Specification has been certified. For the Constructor or Fabricator to do work in accordance with Construction Specifications and Design Drawings, it is necessary that these documents have been certified.

[98]

NCA-3370 REVISION OF DESIGN DRAWINGS AND CONSTRUCTION SPECIFICATION

Design Documents issued for use in construction shall be revised to reflect any change in the Design. Changes to Design Documents shall be reviewed and certified in accordance with NCA-3360.

NCA-3380 CERTIFICATION OF CONSTRUCTION REPORT

The Construction Report shall be evaluated by the Designer, who shall certify that the Construction Report conforms to the requirements of Division 2 and the Design Specification. He shall also provide any supplemental analysis needed to substantiate this evaluation. Prior to certification, he shall review the file of as-built, design, shop, and field drawings to establish that the list provided by the Constructor in the Construction Report corresponds to the as-built, design, shop, and field drawings which will be maintained as a file by

Page 24

the Owner. Distribution of the Construction Report is shown in Table NCA-3200-1.

NCA-3400 RESPONSIBILITIES OF AN N CERTIFICATE HOLDER - DIVISION 2

[98]

NCA-3420 CATEGORIES OF THE N CERTIFICATE HOLDER'S RESPONSIBILITIES

The N Certificate Holder is responsible for:

- (a) obtaining an N Certificate (NCA-3430);
- (b) constructing the components and parts in accordance with the Design Drawings and Construction Specification(s) and in accordance with this Section;
- (c) qualification of Metallic Material Organizations (NCA-3800);
- (d) qualification of Manufacturers of nonmetallic material (NCA-3900);
- (e) establishing and maintaining a Quality Assurance Program (NCA-3460);

- (f) documenting a Quality Assurance Program (NCA-3462);
- (g) filing the Quality Assurance Manual (NCA-3463);
- (h) preparing construction procedures (NCA-3451);
- (i) preparing shop and field drawings (NCA-3452);
- (j) preparing the Construction Report (NCA-3454);
- (k) obtaining agreement with an Authorized Inspection Agency (NCA-8130);
- (l) Data Reports (NCA-3455);
- (m) document distribution as shown in Table NCA-3200-1;
- (n) structural integrity testing (CB-6000, CC-6000);
- (o) making available to the Inspector the documents specified by this Section and those requested by him to assure compliance with Code requirements;
- (p) review of Certified Material Test Reports and Certificates of Compliance for materials (NCA-1220) used by him;
- (q) preparation, accumulation, control, and protection of required records while in his custody (Table NCA-3200-1);
- (r) documentation of review and approval of material used by him as permitted by NCA-1140(e).

[98]

NCA-3430 OBTAINING A CERTIFICATE

An N Certificate (NCA-8100) shall be obtained for the construction of any concrete reactor vessel or containment intended to be in compliance with the requirements of this Section and to be stamped with an N Code Symbol.

NCA-3440 COMPLIANCE WITH THIS SECTION

The N Certificate Holder has the responsibility for constructing the concrete reactor vessel or concrete containment in accordance with the Design Drawings and Construction Specification and in accordance with this Section. For Division 2 construction, the N Certificate Holder's responsibilities do not include design of the component.

NCA-3450 CONSTRUCTION DOCUMENTS

NCA-3451 Construction Procedures

Construction Procedures give sufficient detailed information about the methods of construction and fabrication to enable those reviewing the procedures to determine whether the requirements of the Design Specification, the Construction Specification, and the Design Drawings will be satisfied. Construction procedures will include test procedures to be performed by the Certificate Holder that are needed to establish conformance with the requirements of the documents listed in this Article. Distribution of procedures is shown in Table NCA-3200-1.

NCA-3452 Shop and Field Drawings

The Certificate Holder shall provide Shop and Field Drawings. Distribution of Shop and Field Drawings is shown in Table NCA-3200-1.

NCA-3453 Material Documentation

The N Certificate Holder shall assemble records to verify that materials comply with the requirements of this Section and the Construction Specification.

NCA-3454 Contents of the Construction Report

The N Certificate Holder shall provide a Construction Report. The Report shall include the following:

- (a) a summary of construction progress showing key dates of major construction activities;
- (b) a complete and detailed record of all reactor vessel or containment acceptance testing;
- (c) a summary of quality control records for components and parts;

Page 25

- (d) a list of as-built, design, field, and shop drawings showing the latest revision used for construction and date;
- (e) a summary of deviations (nonconformances) giving a brief description of the nature of the deviations (nonconformances) and the corrective actions and the date when the corrective actions were taken;
- (f) distribution and approvals as shown in Table NCA-3200-1.

NCA-3455 Data Report

The N Certificate Holder shall certify by signing Form C-1, Appendix V, Division 2 that all details of materials, construction, and workmanship of the component conform to this Section and the Construction Specification. Distribution of the Data Reports is shown in Table NCA-3200-1.

NCA-3460 RESPONSIBILITY FOR QUALITY ASSURANCE

NCA-3461 Scope of Responsibilities for Quality Assurance

(a) The N Certificate Holder shall be responsible for surveying, qualifying, and auditing suppliers of subcontracted services (NCA-3125), including nondestructive examination contractors and Material Organizations. Material Organizations holding a Quality System Certificate (Materials) and Certificate Holders whose scope includes supply or manufacture and supply of material need not be surveyed nor audited for work or material covered by the scope of their Certificate. Subcontractors holding an appropriate Certificate need not be surveyed nor audited for work within the scope of the subcontractor's certificate.

(b) An N Certificate Holder may qualify vendors of subcontracted services other than those requiring a Certificate, such as Material Organization, for another Certificate Holder doing work for that N Certificate Holder. The qualification documentation shall be supplied to the other Certificate Holder prior to their use of the subcontracted service or Material Organization.

NCA-3462 Documentation of Quality Assurance Program

The N Certificate Holder shall be responsible for documenting its Quality Assurance Program (NCA-4134).

NCA-3463 Filing of Quality Assurance Manual

The N Certificate Holder shall file with the Authorized Inspection Agency (NCA-5121) copies of the Quality Assurance Manual. The N Certificate Holder shall keep a copy on file available to the Inspector (NCA-5122).

NCA-3500 RESPONSIBILITIES OF AN N CERTIFICATE HOLDER - DIVISION 1

[98]

NCA-3520 CATEGORIES OF THE N CERTIFICATE HOLDER'S RESPONSIBILITIES

The N Certificate Holder's responsibilities include the following:

- (a) obtaining an N Certificate (NCA-3530);
- (b) compliance with this Section (NCA-3540);
- (c) achievement of structural integrity (NCA-3540);

- (d) provision of a Design Report (NCA-3550) when one is required including:
 - (1) stress analysis of parts (NCA-3552);
 - (2) stress analysis of appurtenances (NCA-3553);
 - (3) reconciliation of Design Drawing changes with Design Report (NCA-3554);
 - (4) certification of Design Report (NCA-3555);
 - (5) availability of Design Report and its documentation of review to Inspector (NCA-3557);
 - (6) provision of Design Report to Owner or his designees for review, and documentation of review (NCA-3556);
 - (7) filing at the site of installation the Design Report or Certified Design Report Summary.
 - (e) qualification of Material Organizations and suppliers of subcontracted services (NCA-3561);
 - (f) establishing and maintaining a Quality Assurance Program (NCA-3560 and NCA-3562);
 - (g) documenting a Quality Assurance Program (NCA-3562);
 - (h) filing the Quality Assurance Manual (NCA-3563);
 - (i) Data Reports (NCA-3570);
 - (j) obtaining an agreement with an Authorized Inspection Agency (NCA-8130);
 - (k) making available to the Inspector the documents specified by this Section and those requested by him to assure compliance with Code requirements;
 - (l) review of Certified Material Test Reports and Certificates of Compliance for materials (NCA-1220) used by him;
 - (m) preparation, accumulation, control, and protection of required records while in his custody (NCA-4134.17);
-

Page 26

- (n) documentation of review and approval of material used by him as permitted by NCA-1140(e);
 - (o) subcontracting (NCA-3125) for materials, design, fabrication, installation, examination, testing, and inspection. The N Certificate Holder shall retain overall responsibility, including certification and stamping.
- [98]

NCA-3530 OBTAINING A CERTIFICATE

An N Certificate (NCA-8100) shall be obtained for the construction of any item intended to be in compliance with the requirements of this Section and to be stamped with an N Code Symbol. An N Certificate Holder may do all of the work of an NPT or NA Certificate Holder at the location shown on his Certificate, provided that the scope of work is included in this Certificate.

NCA-3540 COMPLIANCE WITH THIS SECTION

The N Certificate Holder has the responsibility for the structural integrity using the Design Specification as a basis of design, complying with this Section, and furnishing a Design Report if required.

NCA-3550 REQUIREMENTS FOR DESIGN OUTPUT DOCUMENTS

NCA-3551 General

The drawings used for construction shall comply with the Design Specifications and the rules of this Section and shall be in agreement with the other Design Output Documents.

⁴ See Appendix C of Division 1.

NCA-3551.1 Design Report.⁴

The drawings used for construction shall be in agreement with the Design Report before it is certified and shall be identified and described in the Design Report. It is the responsibility of the N Certificate Holder to furnish a Design Report for each component and support, except as provided in NCA-3551.2 and NCA-3551.3. The Design Report shall be certified by a Registered Professional Engineer when it is for Class 1 components and supports, Class CS core support structures, Class MC vessels and supports, Class 2 vessels designed to NC-3200 (NC-3131.1), or Class 2 or Class 3 components designed to Service Loadings greater than Design Loadings. A Class 2 Design Report shall be prepared for Class 1 piping 1 in. nominal pipe size (DN 25) or smaller which is designed in accordance with the rules of Subsection NC.

NCA-3551.2 Load Capacity Data Sheet.

The Load Capacity Data Sheet shall state the load capacity of the support and identify the tests and calculations used to establish the load capacity. The Load Capacity Data Sheet shall adequately identify the support. The Load Capacity Data Sheet for supports for Class 1 components, Class MC vessels, and Class 2 vessels designed to NC-3200 shall be certified by a Registered Professional Engineer qualified in accordance with the requirements of Appendix XXIII of Section III Appendices. The Load Capacity Data Sheet shall specify the organization responsible for retaining the data substantiating the stated load capacity. Such data shall be on file and available for review.

NCA-3551.3 Certified Design Report Summary.

For standard supports designed by analysis, a Certified Design Report Summary may be furnished in lieu of a Design Report when the manufacturer of the standard support provides his own Design Specification [NCA-3256(b)]. The Design Report used to justify the Certified Design Report Summary shall be certified by a Registered Professional Engineer. The Certified Design Report Summary shall include NCA-3551.3(a) through NCA-3551.3(g) below.

- (a) A description or sketch of the Standard Support including the manufacturer's catalog item number or identification number.
- (b) Identification and location of the Standard Support manufacturer's applicable Design Specification.
- (c) Identification and location of the Standard Support manufacturer's applicable Design Report.
- (d) The classification (Class 1, 2, 3, or MC or combination) of the Standard Support.
- (e) A summary of allowable loads, temperatures, and associated Service Level Limits which the designer of the piping system or other component may use in his design.
- (f) Applicable Code Edition and Addenda.
- (g) Date of Certification.

NCA-3552 Design Output Documents for Parts

When the N Certificate Holder purchases parts from an NPT Certificate Holder, it is the responsibility of the N Certificate Holder to provide or cause to be provided the calculations for the parts and to incorporate them into the Design Output Documents.

Page 27

NCA-3553 Design Output Documents for Appurtenances

The Design Output Documents for each appurtenance which is to be attached to a completed component shall be provided unless they are already included in the component Design Output Documents.

NCA-3554 Modification of Documents and Reconciliation With Design Report

Any modification of any document used for construction, from the corresponding document used for design analysis,

shall be reconciled with the Design Report by the person or organization responsible for the design. A revision or addenda to the Design Report shall be prepared and (if required by NCA-3551.1) certified to indicate the basis on which this has been accomplished. All such revised documentation shall be filed with the completed Design Report.

NCA-3555 Certification of Design Report

(a) The Design Report for Class 1 components and supports, Class CS core support structures, Class MC vessels and supports, Class 2 vessels designed to NC-3200 (NC-3131.1), or Class 2 or Class 3 components designed to Service Loadings shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices. The Design Report shall be certified only after all design requirements of this Section have been met. Such Registered Professional Engineers shall be other than the individuals certifying the Design Specifications (NCA-3255) but are not required by these rules to be independent of the organization holding the Certificate.

(b) It is the intent of this Section that the certification of the Design Report shall in no way relieve the N Certificate Holder of the responsibility for the structural integrity of the completed item for the conditions stated in the Design Specifications.

NCA-3556 Submittal of Design Report for Owner Review

The N Certificate Holder shall submit to the Owner or his designee a copy of the completed Design Report or all components and supports for review and documentation of review to the extent required by NCA-3260.

NCA-3557 Availability of Design Report

The N Certificate Holder shall make a copy of the completed Design Report, Load Capacity Data Sheets, Certified Design Report Summaries, and the drawings used for construction available to the Inspector.

NCA-3560 RESPONSIBILITY FOR QUALITY ASSURANCE

NCA-3561 Scope of Responsibilities

(a) The N Certificate Holder shall be responsible for surveying, qualifying, and auditing suppliers of subcontracted services (NCA-3125), including nondestructive examination contractors and Material Organizations. Material Organizations holding Quality System Certificates (Materials), and Certificate Holders whose scope includes supply or manufacture of materials, need not be surveyed nor audited for work or material covered by the scope of their Certificate. Subcontractors holding an appropriate Certificate of Authorization need not be surveyed nor audited for work within the scope of the subcontractor's Certificate. N or NV Certificate Holders may supply replacement material without material supply being shown in the scope of their Certificate provided supply of replacement material is included in their Quality Assurance Program, the replacement material conforms to all applicable requirements of this Section, and are exclusively for incorporation into items originally manufactured or fabricated and furnished by the N or NV Certificate Holders under their Certificate.

(b) An N Certificate Holder may qualify vendors of subcontracted services (NCA-3125) other than those requiring a Certificate of Authorization, such as Material Organization, for another Certificate Holder doing work for that N Certificate Holder. The qualification documentation shall be supplied to the other Certificate Holder prior to their use of the subcontracted service or Material Organization.

(c) An N Certificate Holder may subcontract furnace brazing operations involving uniform heating to an organization not holding a Certificate, provided:

(1) the work performed is within the scope of activities of the N Certificate Holder's Certificate;

(2) the N Certificate Holder's Quality Assurance Program shall provide for the subcontracting of furnace brazing operations, including Authorized Inspection, and these provisions shall be acceptable to the N Certificate Holder's Authorized Inspection Agency;

(3) the N Certificate Holder's Quality Assurance Program provides for surveillance by the N Certificate

Holder at his subcontractor's facility during the brazing operation;

(4) the N Certificate Holder shall be responsible for surveying and accepting the Quality System Programs of the subcontractor;

(5) the N Certificate Holder shall assure that the subcontractor uses written procedures and brazing operators that have been qualified as required by the Code;

(6) the N Certificate Holder shall be responsible for controlling the quality and for assuring that all materials and parts which are submitted to the Inspector for acceptance, including those brazed by subcontractors, conform to all applicable requirements of this Section.

NCA-3562 Documentation of Quality Assurance Program

The N Certificate Holder shall be responsible for documenting its Quality Assurance Program (NCA-4134).

NCA-3563 Filing of Quality Assurance Manual

The N Certificate Holder shall file with the Authorized Inspection Agency (NCA-5121) copies of the Quality Assurance Manual. The N Certificate Holder shall keep a copy on file available to the Inspector (NCA-5122).

NCA-3570 DATA REPORT

The N Certificate Holder shall certify compliance with this Section by signing the appropriate Data Report including stamping (NCA-8000).

NCA-3600 RESPONSIBILITIES OF AN NPT CERTIFICATE HOLDER

NCA-3620 CATEGORIES OF THE NPT CERTIFICATE HOLDER'S RESPONSIBILITIES

The responsibilities of an NPT Certificate Holder include the following:

- (a) obtaining an NPT Certificate (NCA-3630);
- (b) compliance with this Section (NCA-3640);
- (c) qualification of Material Organizations and suppliers of subcontracted services (NCA-3661);
- (d) establishing and maintaining a Quality Assurance Program (NCA-3660);
- (e) documenting a Quality Assurance Program (NCA-3662);
- (f) filing the Quality Assurance Manual (NCA-3663);
- (g) Data Reports (NCA-3670);
- (h) contributing information to the Constructor needed for the preparation of the Construction Report for Division 2 construction (NCA-3454);
- (i) obtaining agreement with an Authorized Inspection Agency (NCA-8130);
- (j) fabricating parts assigned to him in accordance with the Design Drawings, Construction Specification(s), and in accordance with this Section;
- (k) preparing construction procedures and shop and field drawings;
- (l) distribution of documents for Division 2 construction as shown in Table NCA-3200-1;
- (m) making available to the Inspector the documents specified by this Section and those requested by him to assure compliance with Code requirements;
- (n) review of Certified Material Test Reports and Certificates of Compliance for materials (NCA-1220) used by him;

- (o) preparation, accumulation, control, and protection of required records while in his custody (NCA-4134.17);
- (p) documentation of review and approval of material used by him as permitted by NCA-1140(e);
- (q) provision of Design Report (NCA-3650) for appurtenances when not included in the component Design Report.

NCA-3630 OBTAINING A CERTIFICATE

An NPT Certificate (NCA-8100) shall be obtained for the construction of any item intended to be in compliance with the requirements of this Section and to be stamped with an NPT Code Symbol.

NCA-3640 COMPLIANCE WITH THIS SECTION

The NPT Certificate Holder shall have all work performed in accordance with the applicable requirements of this Section.

NCA-3650 DESIGN DOCUMENTS FOR APPURTENANCES

The Design Documents for each appurtenance which is to be attached to a completed component shall be provided unless they are already included in the component Design Documents.

Page 29

NCA-3660 RESPONSIBILITY FOR QUALITY ASSURANCE

NCA-3661 Scope of Responsibilities

(a) The NPT Certificate Holder shall be responsible for surveying, qualifying, and auditing the Quality System Programs of suppliers of subcontracted services (NCA-3125), including nondestructive examination contractors and Material Organizations. Material Organizations holding a Quality System Certificate (Materials), and Certificate Holders whose scope includes supply or manufacture and supply of materials need not be surveyed nor audited for work or material covered by the scope of their Certificate. Subcontractors holding an appropriate Certificate need not be surveyed nor audited by the NPT Certificate Holder for work within the scope of the subcontractor's Certificate.

(b) An NPT Certificate Holder may subcontract furnace brazing operations involving uniform heating to an organization not holding a Certificate, provided:

(1) the work performed is within the scope of activities of the NPT Certificate Holder's Certificate;

(2) the NPT Certificate Holder's Quality Assurance Program shall provide for the subcontracting of furnace brazing operations, including Authorized Inspection, and these provisions shall be acceptable to the NPT Certificate Holder's Authorized Inspection Agency;

(3) the NPT Certificate Holder's Quality Assurance Program provides for surveillance by the NPT Certificate Holder at his subcontractor's facility during the brazing operation;

(4) the NPT Certificate Holder shall be responsible for surveying and accepting the Quality System Programs of the subcontractor;

(5) the NPT Certificate Holder shall assure that the subcontractor uses written procedures and brazing operators that have been qualified as required by the Code;

(6) the NPT Certificate Holder shall be responsible for controlling the quality and for assuring that all materials and parts which are submitted to the Inspector for acceptance, including those brazed by subcontractors, conform to all applicable requirements of this Section.

NCA-3662 Documentation of Quality Assurance Program

The NPT Certificate Holder shall be responsible for documenting its Quality Assurance Program (NCA-4134).

NCA-3663 Filing of Quality Assurance Program

The NPT Certificate Holder shall file with the Authorized Inspection Agency (NCA-5121) copies of the Quality Assurance Manual. The NPT Certificate Holder shall keep a copy on file available to the Inspector (NCA-5122).

NCA-3670 DATA REPORT

The NPT Certificate Holder shall certify compliance with this Section by signing the appropriate Data Report Form and applying the appropriate stamping (NCA-8000).

NCA-3700 RESPONSIBILITIES OF AN NA CERTIFICATE HOLDER

NCA-3720 CATEGORIES OF THE NA CERTIFICATE HOLDER'S RESPONSIBILITIES

The NA Certificate Holder's responsibilities include the following:

- (a) obtaining an NA Certificate (NCA-3730);
- (b) compliance with this Section (NCA-3740);
- (c) qualification of Material Organizations and suppliers of subcontracted services (NCA-3761);
- (d) establishing and maintaining a Quality Assurance Program (NCA-3760);
- (e) documenting the Quality Assurance Manual (NCA-3762);
- (f) filing the Quality Assurance Manual (NCA-3763);
- (g) Data Reports (NCA-3770);
- (h) obtaining an agreement with an Authorized Inspection Agency (NCA-8130);
- (i) making available to the Inspector the documents specified by this Section and those requested by him to assure compliance with Code requirements;
- (j) review of Certified Material Test Reports and Certificates of Compliance for materials (NCA-1220) used by him;
- (k) preparation, accumulation, control, and protection of required records while in his custody (NCA-4134.17);
- (l) documentation of review and approval of material used by him as permitted by NCA-1140(e).

NCA-3730 OBTAINING A CERTIFICATE

An NA Certificate (NCA-8100) shall be obtained for the installation of any item intended to be in compliance

Page 30

with the requirements of this Section and to be stamped with the NA Code Symbol.

NCA-3740 RESPONSIBILITY FOR COMPLIANCE WITH THIS SECTION

The NA Certificate Holder has responsibility for those activities required to place and attach components to their support structures or join items in accordance with the applicable requirements of this Section.

NCA-3760 RESPONSIBILITY FOR QUALITY ASSURANCE

NCA-3761 Scope of Responsibilities

(a) The NA Certificate Holder shall be responsible for surveying, qualifying, and auditing suppliers of subcontracted services (NCA-3125), including nondestructive examination contractors and Material Organizations. Material Organizations holding a Quality System Certificate (Materials), and Certificate Holders whose scope includes supply or manufacture and supply of materials, need not be surveyed nor audited for work or material covered by the scope of their Certificate. Subcontractors holding an appropriate N, NPT, or NA Certificate need not be surveyed nor audited by the NA Certificate Holder for work within the scope of the subcontractor's Certificate.

(b) An NA Certificate Holder may subcontract furnace brazing operations involving uniform heating to an organization not holding a Certificate, provided:

- (1) the work performed is within the scope of activities of the NA Certificate Holder's Certificate;
- (2) the NA Certificate Holder's Quality Assurance Program shall provide for the subcontracting of furnace brazing operations, including Authorized Inspection, and these provisions shall be acceptable to the Authorized Inspection Agency;
- (3) the NA Certificate Holder's Quality Assurance Program provides for surveillance by the NA Certificate Holder at his subcontractor's facility during the brazing operation;
- (4) the NA Certificate Holder shall be responsible for surveying and accepting the Quality System Programs of the subcontractor;
- (5) the NA Certificate Holder shall assure that the subcontractor uses written procedures and brazing operators that have been qualified as required by the Code;
- (6) the NA Certificate Holder shall be responsible for controlling the quality and for assuring that all materials and parts which are submitted to the Inspector for acceptance, including those brazed by subcontractors, conform to all applicable requirements of this Section.

NCA-3762 Documentation of Quality Assurance Program

The NA Certificate Holder shall be responsible for documenting his Quality Assurance Program (NCA-4134).

NCA-3763 Filing of Quality Assurance Manual

The NA Certificate Holder shall file with his Authorized Inspection Agency (NCA-5121) copies of the Quality Assurance Manual. The NA Certificate Holder shall keep a copy on file available to the Inspector (NCA-5122).

NCA-3770 DATA REPORT

The NA Certificate Holder shall certify compliance with this Section by signing the appropriate Data Report Forms and applying the appropriate stamping (NCA-8000).

NCA-3800 METALLIC MATERIAL ORGANIZATION'S QUALITY SYSTEM PROGRAM

NCA-3810 EXCLUSIONS

Material falling within the small products exclusion of NB-/NC-/ND-/NE-/NF-/ NG-2610 or material which is allowed by this Section to be furnished with a Certificate of Compliance, is exempted from the requirements of NCA-3800, except:

- (a) Certified Material Test Reports or Certificates of Compliance shall meet the requirements of NCA-3862.1.
- (b) For Class 1 construction only, material identification and marking shall meet the requirements of NCA-3856.3.

NCA-3820 ACCREDITATION OR QUALIFICATION OF MATERIAL ORGANIZATIONS

(a) A Material Organization shall be accredited by obtaining a Quality System Certificate issued by the Society verifying the adequacy of the Material Organization's Quality System Program.

Page 31

(b) Alternatively, the Certificate Holder (NCA-3461, NCA-3561, NCA-3661, or NCA-3761) or, when included in its scope of activities, the accredited Material Organization [NCA-3820(a)] may qualify Material Organizations not accredited by the Society by evaluation of the organization's Quality System Program in accordance with the requirements of NCA-3842.

(c) A Certificate Holder may furnish material when stated in the scope of its Certificate. In this case, a Quality System Certificate is not required, nor is the user of the material required to survey, qualify, or audit such a Certificate Holder.

NCA-3830 RESPONSIBILITIES OF MATERIAL ORGANIZATIONS

The Material Organization shall be responsible for establishing, documenting, implementing, and maintaining a Quality System Program in accordance with the requirements of NCA-3850, and as applicable to its scope of activities:

- (a) establishing and maintaining measures for the traceability of material or source material while under its control (NCA-3856);
- (b) controlling quality during manufacture, including control of testing, examination, repair, and treatment of the material or source material (NCA-3857, NCA-3858);
- (c) evaluating, qualifying, and auditing Material Organizations (NCA-3842), as provided by NCA-3820(b), except when the party holds a Quality System Certificate which covers the operations performed;
- (d) approving and controlling operations performed by suppliers of source material and subcontracted services (NCA-3855);
- (e) preparing Certified Material Test Reports and Certificates of Compliance (NCA-3860).

NCA-3840 EVALUATION OF THE PROGRAM

[98]

NCA-3841 Evaluation by the Society

(a) The Society, when requested by the applicant on forms issued by the Society, will arrange for a survey of the Material Organization's Quality System Program for the scope of activities on the application. The Program will be evaluated on the basis of its compliance with the applicable material requirements of this Section and the requirements of this Subarticle. The Quality System Certificate, which is issued for a three year period, will describe and specify the scope and limits of work for which the accredited Material Organization is qualified and will be subject to a planned audit program by the Society. Not later than six months prior to the expiration of the Certificate, the accredited Material Organization shall apply for a renewal evaluation and for issuance of a new Certificate.

(b) The applicant shall supply all information required by forms provided by the Society.

(c) The applicant's Quality System Program shall be accepted by the Society prior to the issuance of a Certificate.

(d) A controlled copy of the accredited Material Organization's Quality System Manual shall be filed with the Society. The Manual shall be the Society's guide for surveying and auditing the accredited Material Organization's continued compliance with the accepted Quality System Program.

(e) The accredited Material Organization shall make available for on-site review by the Society any procedures, process sheets, or drawings as are necessary to understand the Program. Detailed technical procedures will not be approved by the Society. The accredited Material Organization shall keep a controlled copy of the Manual on file and in a place and manner readily available to the Society's audit team.

(f) The accredited Material Organization shall obtain the Society's review and acceptance of proposed revisions to the Quality System Manual prior to implementation.

(g) When the applicant requests that the scope of the Quality System Certificate include qualification of non-accredited Material Organizations (NCA-3842), this activity shall be included in the Manual, and will be reviewed by the Society.

(h) When the applicant requests that the scope of the Quality System Certificate include implementation of NCA-3855.5, Utilization of Unqualified Source Material, this activity shall be included in the Manual and will be reviewed by the Society.

(i) When the applicant requests that the scope of the Quality System Certificate include approval and control of suppliers (NCA-3855.3), this activity shall be included in the Manual and will be reviewed by the Society.

[98]

NCA-3842

NCA-3842 Evaluation by Parties Other Than the Society

NCA-3842.1 Qualification of Material Organizations

(a) The qualification of Material Organizations by parties other than the Society shall be limited to the furnishing of source material, material, or subcontracted services to the accredited Material Organization or Certificate Holder performing the evaluation, or their designee.

Page 32

(b) When a Material Organization has been qualified by an accredited Material Organization or Certificate Holder, it is not necessary for another party to requalify that organization for materials or services that are to be furnished to the party that performed the evaluation.

[98]

NCA-3842.2 Evaluation of the Qualified Material Organization's Program by Accredited Material Organizations or Certificate Holders.

Evaluation of a Material Organization's Quality System Program by parties other than the Society, as provided by NCA-3820(b), shall be performed in accordance with the requirements of NCA-3842.2(a) through (h) below.

(a) The Quality System Program shall be surveyed, accepted, and audited by the party performing the evaluation on the basis of its compliance with the applicable material requirements of this Section and the requirements of NCA-3850.

(b) The Quality System Manual (NCA-3853.1) shall be the party's guide for surveying and auditing the qualified Material Organization's continued compliance with the accepted Quality System Program.

(c) The qualified Material Organization shall make available for on-site review by the party performing the evaluation any procedures, process sheets, or drawings as are necessary to understand the Program. The qualified Material Organization shall keep a controlled copy of the Manual on file and in a place and manner readily available to the party performing the audit.

(d) The qualified Material Organization shall notify purchasers of material, source material, or subcontracted services accepting its Program of proposed revisions to its Quality System Manual. The party accepting the Program shall evaluate and accept such revisions prior to the implementation of the revisions on purchased materials or services.

(e) When the qualified Material Organization's scope of activities includes utilization of unqualified source material (NCA-3855.5), this activity shall be included in the Quality System Manual, and shall be reviewed by the party accepting the Program.

(f) When the qualified Material Organization's scope of activities includes approval and control of suppliers (NCA-3855.3), this activity shall be included in the Quality System Manual, and shall be reviewed by the party accepting the Program. During surveys or audits of qualified Material Organizations, the party performing the evaluation shall review objective evidence that the qualified Material Organization's control of suppliers is adequate to assure compliance with the applicable material requirements of this Section.

(g) Audits by parties performing evaluations of qualified Material Organizations shall meet the following requirements:

(1) The party performing the evaluation shall include audit frequency in their Manual.

(2) Audit frequencies shall be commensurate with the schedule of production or procurement, but shall be conducted at least once triennially during the interval in which materials are controlled or services are performed by the Material Organization being evaluated.

(3) Audits shall meet the requirements of NCA-3859.1(a) through (c).

(h) The party performing the evaluation shall supplement triennial audits with annual audits or performance assessments documenting the effectiveness of the qualified Material Organization's Quality System Program. Performance assessments shall meet the following requirements:

(1) Assessment frequencies shall be commensurate with the schedule of production or procurement, but shall be conducted at least once annually during the interval in which materials or source materials are controlled, or services are supplied by the Material Organization being evaluated.

(2) Assessments shall include a documented review of the qualified Material Organization's history of conditions adverse to quality, nonconformances, and corrective actions.

(3) Assessments shall include a documented review of periodic testing performed since the last assessment to demonstrate conformance of sample materials to selected requirements of the material specification. Such testing shall be conducted during the period since the last assessment by the party performing the evaluation.

[98]

NCA-3850 QUALITY SYSTEM PROGRAM REQUIREMENTS

NCA-3851 Responsibility and Organization

NCA-3851.1 General

(a) The Material Organization shall establish a Quality System Program for the control of quality during manufacture or during other work it proposes to perform, and for the traceability of material or source material under its control. The Program shall be planned, documented, implemented, and maintained in accordance with the requirements of NCA-3850.

(b) The establishment of the Program shall include consideration of the technical aspects and provide for planning and accomplishment of activities affecting quality. The Program shall provide for any special

Page 33

controls, processes, test equipment, tools, and skills to attain the required quality and for verification of quality.

NCA-3851.2 Scope and Applicability

(a) The Quality System Manual shall define the specific activities included in the scope of the work the Material Organization proposes to perform, including any combination of:

(1) Operations performed during the melting and heat analysis, affecting the mechanical properties, conversion from one product form into another product form including applicable dimensional requirements, and certification to the applicable material specification.

(2) Testing, examination, repair, or treatments required by the material specification or the specific applicable material requirements of this Section and certification of the results of such tests, examinations, repairs, or treatments.

(3) Receipt, identification, verification, handling, storage, and shipment of material or source material.

(4) Qualification of Material Organizations permitted by NCA-3820(b).

(5) Approval and control of suppliers of source material or subcontracted services (NCA-3855.3).

(6) Utilization of unqualified source material (NCA-3855.5).

(b) The Program shall include measures to comply with all requirements of this Subarticle, to the extent necessary to assure compliance with the requirements of this Section.

NCA-3851.3 Organization

(a) The organizational structure for executing the Program may take various forms, provided the persons and organizations assigned the quality assurance functions have the required authority and organizational freedom.

(b) Persons or organizations responsible for defining and measuring the overall effectiveness of the Program shall:

(1) be designated;

(2)

- (3) have direct access to responsible management at a level where appropriate action can be initiated;
- (4) report regularly on the effectiveness of the Program.

(c) The organizational structure, functional responsibilities, levels of authority, and lines of communication for activities affecting quality shall be documented. Persons or organizations responsible for assuring that an appropriate Quality System Program has been established and verifying that activities affecting quality have been correctly performed shall have sufficient authority, access to work areas, and organizational freedom to:

- (1) identify quality problems;
- (2) initiate, recommend, or provide solutions to quality problems through designated channels;
- (3) verify implementation of solutions;
- (4) assure that further processing, delivery, or use is controlled until proper disposition of a nonconformance, deficiency, or unsatisfactory condition has occurred.

(d) Individuals or groups assigned the responsibility of checking, auditing, or otherwise verifying that production and quality control activities have been correctly performed, shall be independent of the individual or group directly responsible for performing the specific activity. Such persons shall not report directly to the supervisor with immediate responsibility for the work being verified.

(e) Management shall regularly review the status and adequacy of the Program.

NCA-3852 Personnel

NCA-3852.1 Indoctrination, Training, and Qualification of Personnel

(a) Measures shall be established to assure that all personnel performing or managing activities affecting quality are indoctrinated and trained. The assignment of personnel shall be at the discretion of the organization's management. Indoctrination and training measures shall reflect the following requirements:

- (1) Personnel to be indoctrinated or trained shall be identified.
- (2) The extent of indoctrination and training shall be commensurate with the scope, complexity, and nature of the activity as well as the education, experience, and proficiency of the person.
- (3) Personnel shall be indoctrinated in the general criteria, applicable codes, standards, company procedures, Quality System Program requirements, job responsibilities and authority as they relate to a particular function.
- (4) Training shall be provided, as needed, to achieve initial proficiency, maintain proficiency, and adapt to changes in technology, methods, and job responsibilities.

(b) All nondestructive examination personnel shall be qualified in accordance with para. NB-/NC-/ND-/NE-/NF-/NG-5521 of the applicable Subsection.

(c) Personnel who lead audits shall be qualified on the basis of education, experience, training, audit participation, and examination in accordance with the organization's Quality System Program.

Page 34

NCA-3852.2 Personnel Records

(a) Records shall be maintained of the implementation of indoctrination and training of personnel. Records of indoctrination and training may take the form of attendance sheets, training logs, or personnel training records.

(b) Qualification records of all nondestructive examination personnel shall be documented and maintained.

(c) Qualification records of personnel who lead audits shall be documented and maintained and shall include education, experience, audit training and examination, and audit participation used as the basis of qualification.

NCA-3853 Program Documentation

NCA-3853.1 Quality System Manual

(a) The Quality System Program shall be described and summarized in a Quality System Manual which shall be a major basis for demonstration of compliance with the rules of this Section.

(b) The Program documented in the Manual shall be implemented by written procedures which are maintained either separately or in the Quality System Manual.

(c) Detailed technical procedures and processes, such as those for nondestructive examination, are not considered part of the Manual; however, the controls of such procedures and processes shall be covered by the Manual.

NCA-3853.2 Procedures, Instructions, and Drawings

(a) Activities affecting quality shall be prescribed by and performed in accordance with documented instructions, procedures, or drawings of a type appropriate to the circumstances.

(b) These documents shall include or reference appropriate acceptance criteria for determining that the prescribed activities have been satisfactorily completed.

NCA-3853.3 Document Control.

The preparation, issue, and change of documents that specify quality requirements or prescribe activities affecting quality, such as Quality System Program Manuals, purchase specifications, instructions, procedures, and drawings shall be controlled to assure that the correct documents are being used at the location where the activity is performed. Such documents, including changes thereto, shall be reviewed for adequacy and approved for release by authorized personnel.

NCA-3853.4 Quality Assurance Records.

Records that furnish documentary evidence of quality shall be specified, prepared, controlled, and maintained. Records shall be legible, identifiable, and retrievable. Records shall be protected against damage, deterioration, or loss. Requirements and responsibilities for record transmittal, distribution, retention, maintenance, and disposition shall be established and documented.

NCA-3853.5 Records of Examinations and Tests.

All characteristics required to be reported by the material specification and this Section shall be verified and the results recorded. Records shall be traceable to the document and revision to which an inspection, examination, or test was performed.

NCA-3855 Control of Purchased Materials, Source Materials, and Services

NCA-3855.1 General

(a) Measures shall be established to assure that all purchased material, source material, and subcontracted services conform to the requirements of this Section.

(b) Welding material used in the repair of material or source material shall be controlled in accordance with this Section.

(c) These measures shall be designed to prevent the use of incorrect or defective material or source material, or materials which have not received the required examinations or tests.

NCA-3855.2 Sources of Material, Source Material, and Services

(a) Material shall be furnished by a Material Organization [NCA-3820(a) or NCA-3820(b)], or by a Certificate Holder [NCA-3820(c)].

(b) Except as provided in NCA-3855.5, source material shall be furnished by a Material Organization, by an approved supplier (NCA-3855.3), or by a Certificate Holder.

(c) Services including performance and certification of operations, processes, the results of tests, examinations, repairs, or treatments required by the material specification or by this Section shall be furnished by a Material Organization, by an approved supplier, or by a Certificate Holder.

NCA-3855.3 Approval and Control of Suppliers of Source Material and Services

(a) The Material Organization or Certificate Holder shall be responsible for the approval of and control of activities performed by suppliers of source materials and subcontracted services. Such control shall provide for source evaluation and selection, evaluation of objective evidence of quality, audit, and examination of items and services upon delivery, in accordance with requirements documented in the Material Organization's or Certificate Holder's Program.

Page 35

(b) The Material Organization or Certificate Holder shall be responsible for establishing and verifying that the supplier's controls applicable to the activities performed are adequate by:

(1) surveying and auditing the supplier's established quality system which is consistent with the requirements of this Subarticle, or

(2) having the supplier perform the activities in accordance with controls established by the Material Organization's or Certificate Holder's Program.

(c) The Material Organization or Certificate Holder shall be responsible for assuring that all material and activities conform to all applicable requirements of this Section.

NCA-3855.4 Procurement Document Control

(a) Procurement documents shall include requirements necessary to assure compliance with the requirements of this Section.

(b) Except as provided in NCA-3855.5, procurement documents shall require material, source material, or subcontracted services to be furnished in accordance with the applicable requirements of this Subarticle.

(c) Procurement documents shall require approved suppliers to reference the accepted quality system or controls established by the Material Organization or Certificate Holder on documentation that accompanies the source material or services furnished.

(d) Procurement documents that specify quality requirements or prescribe activities affecting quality shall be reviewed for adequacy and approved for release by authorized personnel.

NCA-3855.5 Utilization of Unqualified Source Material

(a) As an alternative to NCA-3855.2(b), when included in its scope of activities as permitted by the provisions of this Subarticle, a Material Organization may accept certification of the requirements of the material specification which must be performed during the melting, heat analysis, and heat treatment of the material, and may use or furnish unqualified source material, provided the requirements of NCA-3855.5(a)(1) through (4) below are met:

(1) No welding with filler metal has been performed on the unqualified source material.

(2) The Material Organization performs or subcontracts a product analysis to verify the chemical composition of each piece of unqualified source material.

(3) The Material Organization performs or subcontracts all other requirements of the material specification on each piece of unqualified source material. Where Certificates of Compliance [NCA-3862.1(g)] are acceptable, testing of each piece is not required. Alternatively, the Material Organization may perform or subcontract all other requirements of the material specification on each heat and lot of unqualified source material provided:

(a) A Certified Material Test Report is provided with the unqualified source material.

(b) The unqualified source material is traceable to the Certified Material Test Report.

(c) Procurement documents require that suppliers of unqualified source material establish written procedures for identifying source materials in a manner that provides traceability to the Certified Material Test Report.

(d) The Material Organization reviews and accepts the supplier's identification and traceability procedures and verifies compliance with the procedures at a frequency commensurate with the schedule of production or procurement, but at least once triennially.

(e) Upon receipt, the Material Organization shall verify by review of objective evidence, that the requirements of the procurement document have been met.

(4) The provisions of (a)(1) through (a)(3) above are performed in accordance with the Material Organization's Quality System Program.

(b) The provisions of (a)(1) through (a)(3) above may be performed by the Certificate Holder in accordance with his Quality Assurance Program.

NCA-3856 Identification, Marking, and Material Control

NCA-3856.1 General

(a) Control shall be established to assure that only correct and accepted material or source material is used. Identification shall be maintained on these materials or on documents traceable to these materials, or in a manner which assures that the identification is established and maintained.

(b) Measures shall be established for controlling and identifying material or source material, including that which is partially processed, throughout the manufacturing process, during the performance of tests, examinations, repairs, and treatments, and during receipt, storage, handling, and shipment.

(c) Identification marking shall be transferred to all pieces when material or source material is divided.

NCA-3856.2 Marking Method.

Materials and source materials shall be marked by any method acceptable to the purchaser which will not result in harmful contamination or sharp discontinuities and will identify these materials in accordance with the material specification.

Page 36

[98]

NCA-3856.3 Identification of Completed Material

(a) The identification of completed material shall consist of marking the material with the applicable specification and grade of the material, the heat number or heat code of the material, and any additional marking required by this Section to facilitate traceability of the material to reports of the results of all tests and examinations performed on the material.

(b) For those materials where Certificates of Compliance [NCA-3862.1(g)] are allowed, heat-number identification need not be indicated on the material or the Certificate.

(c) A marking symbol or code may be used which identifies the material, provided such code or symbol is explained in the Certified Material Test Report (NCA-3862.1) or Certificate of Compliance [NCA-3862.1], as applicable.

(d) All requirements of the material specification shall be met except where specifically exempted or superseded by a provision of this Section. When special requirements or provisions of this Section conflict with the requirements of the material specification, the material specification and grade number shall be followed with an asterisk (*) to indicate that the material specification has been revised as shown on the material certification.

(e) For nonferrous materials manufactured in accordance with material specifications which do not provide for heat identification, the material shall be marked with a symbol or code that identifies the lot, as defined in the material

specification, with the Certified Material Test Report.

(f) Except as required by the material specification, bolts and nuts 1 in. (25 mm) nominal diameter and smaller and other products where the largest space available for marking is less than 1 in. (25 mm) in any one direction need not be individually marked, provided they are packed in packages or containers which shall be clearly identified by legible marking to ensure positive identification of the material. The markings on the containers shall identify the material with the Certificate of Compliance [NCA-3862.1(g)] or Certified Material Test Report (NCA-3862.1), as applicable.

[98]

NCA-3856.4 Welding and Brazing Materials Identification.

Welding and brazing materials shall be clearly identified by legible marking on the package or container to ensure positive identification of the material. The marking shall include the heat or lot number as applicable, a control marking code which identifies the material with the Certified Material Test Report (NCA-3862.1), and other information such as specification, grade and classification number, Material Organization's name, and trade designation.

NCA-3857 Process Control

NCA-3857.1 General.

Processes affecting quality of materials, source materials, or services shall be controlled. Special processes that control or verify quality, such as those used in welding, heat treating, or nondestructive examination, shall be performed by qualified personnel using qualified procedures in accordance with specific requirements.

NCA-3857.2 Manufacturing Process Control.

Operations shall be performed under a controlled system such as process sheets, shop procedures, checklists, travelers, or equivalent procedures. Measures shall be established to ensure that processes, including heat treatment, are controlled in accordance with the material specification and the rules of this Section.

NCA-3857.3 Welding.

When welding is required in the repair of material or source material, it shall be performed in accordance with procedures and by welders or welding operators qualified in accordance with this Section and Section IX. The qualification of procedures and welders or welding operators shall be documented.

NCA-3857.4 Handling, Storage, Shipping, and Preservation.

Instructions shall be established for handling, storage, shipping, and preservation of material or source material to prevent damage or deterioration.

NCA-3858 Control of Examinations, Tests, and Nonconforming Material

NCA-3858.1 Inspection, Examination, and Test Control

(a) Inspections, examinations, and tests shall be established to assure conformance with the requirements of the material specification and this Section.

(b) Inspections or examinations required to verify conformance of material, source material, or an activity to specified requirements shall be planned. Characteristics to be inspected or examined, and inspection or examination methods to be employed, shall be specified. Inspection or examination results shall be documented.

(c) Tests required to verify conformance to specified requirements shall be planned. Characteristics to be tested and test methods to be employed shall be specified. Test results shall be documented and their conformance with acceptance criteria shall be evaluated.

NCA-3858.2 Control of Measuring and Test Equipment

(a) Procedures shall be in effect to assure that tools, gages, instruments, and other measuring and testing devices used to verify compliance with the material specification and this Section are calibrated and properly adjusted at specific periods or use intervals to maintain accuracy within necessary limits. Periodic checks on equipment may be performed to determine that calibration is maintained.

(b) Calibration shall be against certified equipment having known valid relationships and documented traceability to nationally recognized standards, where such standards exist. If no known nationally recognized standards exist, the basis for calibration shall be documented.

(c) Control measures shall include provisions for measuring and test equipment identification and for determining calibration status by equipment marking or on records traceable to the equipment.

NCA-3858.3 Discrepancies in Measuring or Testing Equipment

(a) When discrepancies in excess of tolerances for measuring or testing equipment are found at calibration, appropriate corrective action shall be taken, and material measured or tested since the previous calibration shall be reviewed to determine that all applicable requirements have been met.

(b) When periodic checks on equipment are performed to determine that calibration is maintained, potential material or source material discrepancies need only be resolved to the previous check, provided:

- (1) the methods used and frequency of periodic checking are described in calibration procedures; and
- (2) the calibration discrepancy was found by periodic check.

NCA-3858.4 Inspection and Test Status.

Measures shall be established so that the status and results of any required inspections, examinations, or tests can be determined at any time. Status shall be maintained through indicators such as physical location and tags, marking, shop travelers, stamps, inspection records, or other suitable means. The authority for application and removal of such indicators shall be specified.

NCA-3858.5 Control of Nonconforming Material

(a) Adequate control measures shall be established to prevent the use of material that does not conform to the requirements of the material specification and this Section.

(b) Material or source material with nonconformances shall be identified, segregated when practical, and reviewed for acceptance, rejection, or repair in accordance with documented procedures. The responsibility and authority for the disposition of nonconformances in these materials shall be defined.

(c) Repaired material or source material shall be reexamined in accordance with applicable procedures.

(d) Measures which control further processing of nonconforming or defective material or source material, pending a decision on its disposition, shall be established and maintained. These control measures shall extend to notification of other affected organizations, as appropriate.

NCA-3859 Audits and Corrective Action

NCA-3859.1 Audits

(a) Audits shall be performed in accordance with written procedures or checklists by personnel not having direct responsibility in the areas being audited.

(b) Audit results shall be documented by auditing personnel for review by management having responsibility in the area being audited.

(c) Procedures shall include provisions for documentation of corrective action taken in response to deficiencies.

Follow-up action, including re-audit of deficient areas where indicated, shall be taken to verify implementation of such corrective actions.

(d) In addition to audits of Material Organizations and suppliers, a comprehensive system of planned and periodic internal audits shall be carried out to assure compliance with all aspects of the Quality System Program and to determine the effectiveness of the Program.

(e) Internal audits shall be performed in accordance with the requirements of (a) through (c) above.

NCA-3859.2 Corrective Action

(a) Measures shall be established to assure that conditions adverse to quality such as failures, malfunctions, deviations, defective material and equipment, nonconformances, and quality system deficiencies, are promptly identified and reported to appropriate levels of management. The measures shall also assure that the cause of conditions adverse to established quality levels be determined and corrected.

(b) The identification of significant or recurring conditions adverse to quality, the cause of condition, and the corrective action taken shall be documented and reported to appropriate levels of management.

(c) These requirements shall also extend to the performance of the approved supplier's corrective action measures.

Page 38

NCA-3860 CERTIFICATION REQUIREMENTS

NCA-3861 Certification Requirements for Material Organizations

(a) The Material Organization whose scope of activities includes NCA-3830 shall provide a Certified Material Test Report or Certificate of Compliance, as applicable (NCA-3862), for the material.

(1) The certification affirms that contents of the report are correct and accurate and that all test results and operations performed by the Material Organization or its subcontractors are in compliance with the material specification and the specific applicable material requirements of this Section.

(2) Chemical analyses, tests, examinations, and heat treatments required by the material specification that were not performed shall be listed on the Certified Material Test Report or Certificate of Compliance, as applicable, or may be listed on an identified attachment.

(3) When the Material Organization's scope of activities includes product form conversion, the Material Organization shall also certify that the material conforms to the applicable dimensional requirements.

(b) The Material Organization shall transmit all certifications received from other Material Organizations or approved suppliers in accordance with (a) above, to the purchaser at time of shipment.

(c) The Certificate Holder shall complete all operations not completed by the Material Organization and shall provide a Certified Material Test Report for all operations performed by him or his approved suppliers. The Certificate Holder shall certify that the contents of the report are correct and accurate and that all test results and operations performed by the Certificate Holder or his approved suppliers are in compliance with the requirements of the material specification and this Section. Alternatively, the Certificate Holder shall provide a Certified Material Test Report for the operations it performed and at least one Certified Material Test Report from each of its approved suppliers for the operations they performed.

NCA-3862 Certification of Material

NCA-3862.1 Material Certification

(a) The Certified Material Test Report shall include the actual results of all required chemical analyses, tests, and examinations.

(b) When required chemical analyses (including melting mill heat analysis), heat treatment, tests, examinations, or repairs are subcontracted, the approved supplier's certification for the operations performed shall be furnished as an identified attachment to the Certified Material Test Report.

(c) The Certified Material Test Report shall also include a report of all weld repairs performed on the material as required by this Section. Radiographic film required for the examination of material repair welds shall be included as a part of the Certified Material Test Report, except for those radiographs required for the testing of welding or brazing materials.

(d) When specific times or temperatures (or temperature ranges) of heat treatments are required by material specifications, they shall be reported. When specific times and temperatures (or temperature ranges) are not required by the material specification, a statement of the type of heat treated condition shall be reported. In any case, a statement of the minimum solution annealing temperature is adequate for austenitic stainless steels and high nickel alloys. Additionally, the times and temperatures of postweld heat treatments of weld repaired materials as required by the fabrication requirements of this Section shall be reported.

(e) Reporting of actual dimensions and visual examination results is neither required nor prohibited by this paragraph.

(f) Notarization of the Certified Material Test Report is not required.

(g) A Certificate of Compliance with the material specification, grade, class, and heat treated condition, as applicable, may be provided in lieu of a Certified Material Test Report for material $\frac{3}{4}$ in. nominal pipe size (DN 20) and less (pipe, fittings, flanges, materials for valves and tubes except heat exchanger tubes), bolting 1 in. (25 mm) and less, as applicable.

(h) Material identification shall be described in the Certified Material Test Report or Certificate of Compliance, as applicable. Heat or lot traceability to the Certificate of Compliance is not required.

NCA-3862.2 Quality System Program Statement

(a) When the Material Organization holds a Quality System Certificate, the Material Organization's Quality System Certificate number and expiration date shall be shown on the Certified Material Test Report or Certificate of Compliance, as applicable, or on a certification included with the documentation that accompanies the material.

(b) When the Material Organization has been qualified by a party other than the Society, the revision and date of the applicable written Quality System Program shall be shown on the Certified Material Test Report or Certificate of Compliance, as applicable, or on a certification included with the documentation that accompanies the material.

Page 39

(c) The inclusion of the Quality System Certificate number and expiration date or reference to revision and date of the applicable written Quality System Program shall be considered the Material Organization's certification that all activities have been performed in accordance with the applicable requirements of this Subarticle.

NCA-3900 NONMETALLIC MATERIAL MANUFACTURER'S AND CONSTITUENT SUPPLIER'S QUALITY SYSTEM PROGRAM

NCA-3920 QUALITY SYSTEM CERTIFICATE (NONMETALLIC MATERIALS)

(a) A Nonmetallic Material Manufacturer may obtain a Quality System Certificate (Materials) issued by the Society verifying the adequacy of the Nonmetallic Material Manufacturer's Quality System Program. Alternatively, the Nonmetallic Material Manufacturer shall have his Quality System Program surveyed and qualified by the Constructor or Fabricator of the concrete component.

(b) A Nonmetallic Material Constituent Supplier may obtain a Quality System Certificate (Materials) issued by the Society verifying the adequacy of the Nonmetallic Material Constituent Supplier Identification and Verification Program. Alternatively, the Nonmetallic Material Manufacturer shall be responsible for assuring that the constituents supplied meet the requirements of NCA-3950(b) and NCA-3950(c).

NCA-3923 Evaluation for Quality System Certificates

(a) The Society, when requested by the Nonmetallic Material Manufacturer on forms issued by the Society, will arrange for an evaluation of the applicant's Quality System Program. The Program will be evaluated on the basis of its compliance

for an evaluation of the applicant's Quality System Program. The Program will be evaluated on the basis of its compliance with the applicable material requirements of this Section. The certificate which is issued for a 3 year period will describe and specify the scope and limits of work for which the applicant is qualified and will be subjected to a planned audit program by the Society. Not later than 6 months prior to the expiration of the Certificate, the Nonmetallic Material Manufacturer shall apply for a renewal evaluation and for the issuance of a new Certificate.

(b) The Society, when requested by the Nonmetallic Material Constituent Supplier on forms issued by the Society, will arrange for an evaluation of the applicant's Identification and Verification Program. The Program will be evaluated on the basis of its compliance with the applicable requirements of this Section. The certificate which is issued for a 3 year period will describe and specify the material constituent which the applicant is qualified to supply and will be subject to a planned audit program by the Society. Not later than 6 months prior to the expiration of the Certificate, the Nonmetallic Material Constituent Supplier shall apply for a renewal evaluation and for the issuance of a new Certificate.

NCA-3950 QUALITY PROGRAM REQUIREMENTS

(a) A Nonmetallic Material Manufacturer need not be a Certificate Holder, but his Quality Assurance Program shall conform to the requirements of NCA-4000, except for NCA-4134.2 and NCA-4134.3.

(b) A Nonmetallic Material Constituent Supplier shall meet all requirements of CB-2100 and CB-2200 or CC-2100 and CC-2200.

(c) The requirements for ice and water are limited to those tests required by CB-5225 or CC-5225.

NCA-3960 RESPONSIBILITY

NCA-3961 Constructor or Fabricator

(a) The Constructor or Fabricator responsible for the placement of nonmetallic materials (plastic concrete) shall assure that the plastic concrete meets the requirements of the Construction Specification, and that tests performed by the Manufacturer and Supplier of the nonmetallic materials and constituents meet the requirements of Section III, Division 2.

(b) The Constructor or Fabricator shall survey and qualify the Quality Assurance Program of the Nonmetallic Material Manufacturer if he does not obtain a Quality System Certificate (NCA-3923).

(c) The Constructor or Fabricator shall perform any of the functions required by the NCA-4000 which are not performed by the Manufacturer of plastic concrete. He may elect to perform any other Quality Program functions which would normally be the responsibility of the Manufacturer of plastic concrete.

(d) The Constructor or Fabricator shall make all necessary provisions so that the Authorized Inspector and his Authorized Inspection Agency can make the inspections necessary to comply with this Code.

(e) The functions performed by the Constructor or Fabricator shall be clearly defined and included in his Quality Assurance Program.

Page 40

NCA-3962 Nonmetallic Material Manufacturer

(a) The Nonmetallic Material Manufacturer shall have his Quality Assurance Program surveyed and qualified by the Constructor or Fabricator if he does not obtain a Quality System Certificate.

(b) The Nonmetallic Material Manufacturer, using the constituents, shall assure that the Nonmetallic Material Constituent Suppliers have met all the requirements of NCA-3950(b) and NCA-3950(c).

(c) The functions performed by the Nonmetallic Material Manufacturer shall be clearly defined and included in his Quality Assurance Program.

NCA-3963 Nonmetallic Material Constituent Supplier

If the Supplier does obtain a Quality System Certificate, he is responsible for implementing the Program on which that certificate was issued and meeting the requirements of NCA-3950(b) and NCA-3950(c).

American Society Of Mechanical Engineers

SEC III NCA-4000

ARTICLE NCA-4000 QUALITY ASSURANCE

Page 41

NCA-4100 REQUIREMENTS

NCA-4110 SCOPE AND APPLICABILITY

(a) This Article sets forth the requirements for planning, managing, and conducting Quality Assurance Programs for controlling the quality of activities performed under this Section and the rules governing the evaluation of such Programs prior to the issuance of Certificates for the construction, fabrication, manufacture, and installation of Class 1, 2, 3, CS, MC, CB, and CC items. The Quality Assurance requirements for Material Organizations for all Classes of construction are provided in NCA-3800. The Quality Assurance requirements for Nonmetallic Material Organizations and Constituent Suppliers for all Classes of construction are provided in NCA-3900. Certificate Holders are advised to consult other regulations for Quality Assurance requirements governing activities beyond the scope of this Section.

(b) N-Type Certificate Holders shall comply with the Basic Requirements and Supplements of ASME NQA-1-1989 Edition with 1a-1989, 1b-1991, and 1c-1992 Addenda, Quality Assurance Program Requirements for Nuclear Facilities, as modified and supplemented in NCA-4120(b) and NCA-4134.

NCA-4120 DEFINITIONS

(a) The definitions in NCA-9000 shall apply.

(b) The terms and definitions of NQA-1, Supplement S-1 shall apply except for those listed in (1) through (7) below. For the following terms, the definitions in NCA-9000 shall apply:

(1) *item*

(2) *Owner*

(3) *quality assurance*

(4) *repair*

(5) *rework*

(6) *service*

(7) *use-as-is*

NCA-4130 ESTABLISHMENT AND IMPLEMENTATION

NCA-4131 Material Organizations, Division 1

The requirements of NCA-3800 apply.

NCA-4132 Material Organizations for Division 2

NCA-4132.1 Material Organizations.

The requirements of NCA-3800 apply.

NCA-4132.2 Nonmetallic Material Organizations for Division 2.

The requirements of NCA-3900 apply.

NCA-4132.3 Constituent Suppliers, Division 2.

The requirements of NCA-3900 apply.

NCA-4133 Material Organizations, Division 1

The requirements of NCA-3800 apply.

NCA-4134 N, NV, NPT, and NA Certificate Holders for Class 1, 2, 3, MC, CS, CB, and CC Construction

NCA-4134.1 Organization.

The provisions of NQA-1, Basic Requirement 1 and Supplement 1S-1, shall apply.

NCA-4134.2 Quality Assurance Program

(a) The provisions of NQA-1, Basic Requirement 2 and Supplements 2S-1 and 2S-3, shall apply and the system used to meet these requirements shall be described in the Quality Assurance Manual. The Quality Assurance Manual shall also include a statement of policy and authority indicating management support. The specific responsibilities of the quality assurance organization of the Certificate Holder shall also include the review of written procedures and monitoring of the activities concerned with the Quality Assurance Program as covered in this Article.

Page 44

(b) In lieu of Supplement 2S-2, the qualification of nondestructive examination personnel shall be as required by NX-5520.

(c) The controls used in the Quality Assurance Program shall be documented in the Quality Assurance Manual. The Program need not be in the same format or sequential arrangement as the requirements in this Article, as long as all applicable requirements of this Article have been covered. A copy, including all changes that are made, shall be made available to the Inspector. The Certificate Holder shall make available to the Inspector such drawings and process sheets as are necessary to make the Quality Assurance Program intelligible.

(d) The Certificate Holder shall be responsible for advising its Authorized Inspection Agency of any significant changes which are proposed to be made to the Quality Assurance Manual, and shall have acceptance of the Authorized Inspection Agency's Authorized Nuclear Inspector Supervisor before putting such changes into effect. The Certificate Holder shall be responsible for promptly notifying the Inspector of such accepted changes, including evidence of acceptance by the Authorized Inspection Agency, and for simultaneously reconciling copies of the Quality Assurance Manual.

NCA-4134.3 Design Control

(a) The provisions of NQA-1, Basic Requirement 3 and Supplement 3S-1, shall apply.

(b) Measures shall be established to ensure that applicable requirements of the Design Specifications and of this Section for items are correctly translated into specifications, drawings, procedures, and instructions.

(c) Design documents shall be verified for adequacy and compliance with the Design Specification and this Section.

NCA-4134.4 Procurement Document Control.

The provisions of NQA-1, Basic Requirement 4 and Supplement 4S-1, shall apply, except that procurement documents shall require Suppliers to provide a Quality Assurance Program consistent with the applicable requirements of this Section.

NCA-4134.5 Instructions, Procedures, and Drawings.

The provisions of NQA-1, Basic Requirement 5, shall apply.

NCA-4134.6 Document Control.

The provisions of NQA-1, Basic Requirement 6 and Supplement 6S-1, shall apply.

NCA-4134.7 Control of Purchased Items and Services.

The provisions of NQA-1, Basic Requirement 7 and Supplement 7S-1, shall apply, except that:

(a) Supplement 7S-1, 8.3 is not applicable to the procurement of Authorized Inspection Agency services as required in NCA-8130;

(b) the decision to perform bid evaluation for materials to confirm conformance to procurement documents, required in 7S-1, 4.0, shall remain the responsibility of the Certificate Holder;

(c) changes, waivers, or deviations permitted by 7S-1, 8.2.1(b) shall not be acceptable if they do not meet the requirements of this Section;

(d) resolution of nonconformances identified in 7S-1, 8.2.1(c) shall be in conformance with the requirements of this Section; and

(e) documentary evidence that items conform to the requirements of this Section shall be available at the construction or installation site before use or installation. Requirements for documentary evidence are satisfied for material when the applicable rules of NCA-3800 and NCA-3900 for material certification are met. For stamped items, the requirements are satisfied by a Data Report.

NCA-4134.8 Identification and Control of Items

(a) The provisions of NQA-1, Basic Requirement 8 and Supplement 8S-1, shall apply.

(b) Welding and brazing materials for all Classes of construction shall be controlled.

(c) All characteristics required to be reported by the material specifications and by this Section shall appear on checklists, and each such characteristic shall be examined by accepted procedures as required and the results recorded. Characteristics included on Certified Material Test Reports or Certificates of Compliance need not be duplicated in the checklists. Checklists shall provide for a record that the Certified Material Test Reports and Certificates of Compliance have been received, reviewed, and found acceptable. When the results of the examination or test procedure conducted by the Certificate Holder are necessary to show compliance with material specification or other requirements, the checklists shall show the required range of values. The checklists shall include spaces for: inclusion of document number and revision to which examination or tests were made; a signature, initials, or stamp; the date of the examination performed by the Certificate Holder's representative; an Authorized Nuclear Inspector's signature, initials, or stamp; and the date on which those activities were witnessed.

NCA-4134.9 Control of Processes

(a) The provisions of NQA-1, Basic Requirement 9 and Supplement 9S-1, shall apply.

(b) The Certificate Holder shall prepare instructions, procedures, drawings, checklists, travelers, or other

Page 45

appropriate documents, including the document numbers and revisions to which the process conforms, with space provided for reporting results of completion of specific operations at checkpoints of fabrication, manufacture, or installation. The documents shall include space for: a signature, initials, or stamp; the date that the activity was performed by the Certificate Holder's representative; the Authorized Nuclear Inspector's signature, initials, or stamp; and the date on which those activities were witnessed.

NCA-4134.10 Inspection

(a) The provisions of NQA-1, Basic Requirement 10 and Supplement 10S-1, shall apply, except for para. 3.1 and the requirements of Inservice Inspection.

(b) The Certificate Holder shall prepare process sheets, travelers, or checklists, including the document numbers and revision to which the examination or test is to be performed, with space provided for recording results of examinations and tests. The documents shall include space for: a signature, initials, or stamp; the date that the activity was performed by the Certificate Holder's representative; the Authorized Nuclear Inspector's signature, initials, or stamp; and the date on which those activities were witnessed. The examination checklist for construction of items shall be filled in and completed by the Certificate Holder who applies the appropriate Code Symbol Stamp to the item.

(c) Mandatory hold points at which witnessing is required by the Certificate Holder's representative or the Authorized Nuclear Inspector shall be indicated in the controlling documents (NCA-4134.9). Work shall not proceed beyond mandatory hold points without the consent of the Certificate Holder's representative or the Authorized Nuclear Inspector, as appropriate.

NCA-4134.11 Test Control.

The provisions of NQA-1, Basic Requirement 11 and Supplement 11S-1, shall apply.

NCA-4134.12 Control of Measuring and Test Equipment

(a) The provisions of NQA-1, Basic Requirement 12 and Supplement 12S-1, shall apply.

(b) The Certificate Holder may perform periodic checks on equipment to determine that calibration is maintained. When periodic checking is used, discrepancies need only be resolved to the prior check, provided the discrepancy is discovered by the periodic check. The methods and frequency of periodic checking, when used, shall be included in the Certificate Holder's Quality Assurance Program.

NCA-4134.13 Handling, Storage, and Shipping.

The provisions of NQA-1, Basic Requirement 13 and Supplement 13S-1, shall apply.

NCA-4134.14 Inspection and Test Status.

The provisions of NQA-1, Basic Requirement 14, shall apply for inspections and tests, but not for operating status.

NCA-4134.15 Control of Nonconforming Items.

The provisions of NQA-1, Basic Requirement 15 and Supplement 15S-1, shall apply, except that the definition of *repair* given in this Section shall apply in lieu of *repair* and *rework* given in NQA-1.

NCA-4134.16 Corrective Action

(a) The provisions of NQA-1, Basic Requirement 16, shall apply.

(b) The requirements shall also extend to the performance of the subcontractor's corrective action measures.

NCA-4134.17 Quality Assurance Records

(a) *General.* The provisions of NQA-1, Basic Requirement 17 and Supplement 17S-1, shall apply, except that the requirements for classification in 17S-1, 2.7, retention of records in 17S-1, 2.8, and facility in 17S-1, 4.4 are not applicable. Such records shall be classified and maintained as required by this Section.

(b) *Records Index.* The records shall be indexed. The records and the indices thereto shall be accessible to the Owner, Owner's designee, and Authorized Nuclear Inspector.

(c) *Reproduction of Radiographs.* Radiographs may be reproduced provided the following requirements are met:

(1) the reproduction process shall be subject to the Owner's approval;

(2) when radiographs are reproduced for either an Owner or Certificate Holder, the Quality Assurance Program of the Certificate Holder responsible for the reproduction process shall include a system for controlling and monitoring the accuracy of the process so that the image, when reproduced to its original size, will provide the same information retrieval capability as the original radiograph;

(3) procedures shall contain applicable requirements pertaining to exposure, scanning, focusing, contrast, resolution, and distinguishing film artifacts that might appear as material discontinuities in the reproduced image.

(d) *Lifetime Records.* For Classes 1, 2, CS, MC, CC, and CB, the records listed in Table NCA-4134.17-1 shall be classified as lifetime records. For Class 3, only records 1, 2, 3, 4, 8, 9, 15, and 16 in Table NCA-4134.17-1 shall apply. The Certificate Holder shall be responsible for the retention and maintenance of these

Page 46

records while they are under his control. The Owner shall be responsible for retention and maintenance of those records which are transferred to him.

TABLE NCA-4134.17-1¹
LIFETIME QUALITY ASSURANCE RECORDS

Record	Record
1. Index to lifetime records (NCA-4134.17)	10. Records of post-tensioning sequence, procedure, and loads
2. Code Data Reports (NCA-8400)	11. Heat treatment records [Note (2)]
3. Design Specification (NCA-3250) [Note (3)]	12. Qualification test reports such as for concrete design mixes (CB-2460 and CC-2460) and safety valves (NB-7700)
4. Design Output Documents, Division 1 (NCA-3350 and NCA-3550) [Note (3)]	13. Structural integrity test reports (CB-6260 and CC-6260)
5. Design Report, Division 2	14. Final hydrostatic and pneumatic test results (NCA-5280)
6. Overpressure Protection Report (NB-7200, NC-7200, or ND-7200)	15. Final nondestructive examination reports; final radiographs as specified by the Owner for Section XI applications
7. Construction Specification (NCA-3340)	16. Repair records when required by Code (NX-4130)
8. As-built drawings (NCA-3454)	17. Weld procedures
9. Certified Material Test Reports (CMTR) and documentation providing traceability to location used, if required (NX-4122)	18. Construction Report (NCA-3454)

NOTES:

- (1) Nonconformance reports that affect those records listed shall be incorporated into the record or be retained with the records.
- (2) Either heat treatment charts or certified summaries of time and temperature data may be provided. These data may be included as part of the CMTR.
- (3) For supports designed by Load rating the Load Capacity Data Sheet is the Design Output Document to be maintained as a lifetime quality assurance record. For standard supports designed by analysis and supplied with a Certified Design Report Summary the Certified Design Report Summary is the Design Output Document to be maintained as a Lifetime quality assurance record.

TABLE NCA-4134.17-1¹ LIFETIME QUALITY ASSURANCE RECORDS

TABLE NCA-4134.17-2¹
NONPERMANENT QUALITY ASSURANCE RECORDS

Record	Retention Period
1. QA Program Manual	3 years after superseded or invalidated
2. Design procurement and QA procedures (NCA-4134.5)	3 years after superseded or invalidated
3. Installation and NDE procedures (NX-5112)	10 years after superseded or invalidated
4. Personnel qualification records (NX-5520 and NX-4322)	3 years after superseded or invalidated
5. Purchase orders	10 years after superseded or invalidated
6. Audit and survey reports (NCA-4121 and NCA-4134.18)	3 years after completion of report
7. Final radiographs not covered in Table NCA-4134.17-1, Record 15	10 years after completion
8. Calibration records (NCA-4134.12)	Until recalibrated
9. Process sheets, travelers, or checklists (NCA-4134.10)	10 years after completion
10. Rebar splice test reports (CB-4330 and CC-4330)	10 years after completion of report
11. Joint-welder identification records when such records are used in lieu of physical marking of welds (NX-4322)	10 years after completion of report

NOTE:

(1) Nonconformance reports, which affect those records listed and are not incorporated into the record, shall be retained for the retention period applicable to the record the nonconformance report affects.

TABLE NCA-4134.17-2¹ NONPERMANENT QUALITY ASSURANCE RECORDS

(e) *Nonpermanent Records.* For Classes 1, 2, CS, MC, CC, and CB, the records listed in Table NCA-4134.17-2 shall be classified as nonpermanent records. For Class 3, only records 3, 7, and 8 in Table NCA-4134.17-2 shall apply. The Certificate Holder shall be responsible for their retention for the period specified in Table NCA-4134.17-2. In no case need nonpermanent records be retained for longer than 10 years after completion of applicable Code Data Report.

NCA-4134.18 Audits

(a) The provisions of NQA-1, Basic Requirement 18 and Supplement 18S-1, shall apply.

(b) Results of audits shall be made available to the Authorized Nuclear Inspector.

(c) The audit frequency shall be specified in the Certificate Holder's Quality Assurance Manual. The Certificate Holder's audit frequency shall be commensurate with his schedule of activities and shall be such that each ongoing Code activity is audited at least once annually.

July 1, 1998

AMERICAN SOCIETY OF MECHANICAL ENGINEERS

SEC III NCA-5000

ARTICLE NCA-5000 AUTHORIZED INSPECTION

Page 49

Page 51

NCA-5100 INTRODUCTION

NCA-5110 APPLICABILITY

(a) This Article provides the requirements for the inspection of items constructed in accordance with this Section by the Authorized Inspection Agency.

(b) When preservice examinations are required by this Section inspection of the preservice examinations by the Authorized Inspection Agency shall be in accordance with IWA-2100 of Section XI.

NCA-5120 PERFORMANCE OF INSPECTION

NCA-5121 Authorized Inspection Agency

(a) An Authorized Inspection Agency is one designated by, or is one acceptable to, the appropriate Enforcement Authority of a state of the United States or a province of Canada. The Authorized Inspection Agency shall be accredited by the Society in accordance with the provisions set forth in ASME QAI-1-1995, Qualification for Authorized Inspection.

(b) The Authorized Inspection Agency shall notify the Society when it enters into an agreement with an Owner or a Certificate Holder, or whenever an existing agreement is terminated. The Authorized Inspection Agency shall also notify the Enforcement Authority whenever an agreement with an Owner is written or an Owner's agreement is terminated.

NCA-5122 Authorized Nuclear Inspector Supervisor

The Authorized Inspection Agency shall employ Authorized Nuclear Inspection Supervisors qualified in accordance with ASME QAI-1-1995, Qualification for Authorized Inspection to supervise the Inspectors.

NCA-5123 Authorized Nuclear Inspector

The Authorized Inspection Agency shall also employ Authorized Nuclear Inspectors qualified in accordance with ASME QAI-1-1995, Qualification for Authorized Inspection to perform inspections required by this Section. The inspections required by this Section shall be performed by an Authorized Nuclear Inspector. Any reference to Inspector throughout this Section shall mean Authorized Nuclear Inspector. The Authorized Nuclear Inspector shall not be in the employ of an N Certificate Holder.

NCA-5125 Duties of Authorized Nuclear Inspector Supervisors

(a) Supervisors, in conjunction with Inspectors employed by the same Authorized Inspection Agency (NCA-5121), shall participate in the Society's review of the applicant's Quality Assurance Program (NCA-8160). In those cases where the Supervisor performs the functions of the Inspector, he may represent both during the review of the Program. A Supervisor designated by the Authorized Inspection Agency shall review and accept any proposed modifications to Quality Assurance Manuals before they are put into effect. The Authorized Nuclear Inspector Supervisor shall audit the Inspector's performance at least twice per year at locations where the Certificate Holder is actively engaged in Section III work. The Supervisor shall be available as needed for consultation and support of the local inspection staff. The Supervisor shall maintain supervisory control over one or more Authorized Nuclear Inspectors and shall perform all of the functions and maintain the records required of him in ASME QAI-1-1995, Qualification for Authorized Inspection.

(b) The portion of a Certificate Holder's Quality Assurance Program that involves supply or manufacture

and supply of materials [NCA-3820(e)] shall be audited by the Supervisor at least once each year.

NCA-5130 ACCESS FOR INSPECTION AGENCY PERSONNEL¹

NCA-5131 Access to the Certificate Holder's Facilities

(a) The Certificate Holder shall arrange for the Inspection Agency Personnel to have free access at all times to those locations where Code activities, including those concerned with supply or manufacture of materials, are being performed on an item, when so requested. The Certificate Holder shall keep the Inspector informed of the progress of the work and shall notify him reasonably in advance when the item will be ready for any required tests or inspections.

(b) The Certificate Holder shall provide personnel to accompany the Authorized Nuclear Inspector Supervisor during his required audits.

NCA-5132 Access to the Owner's Facilities

The Owner shall arrange for the Authorized Inspection Agency Personnel to have free access to the Owner's facilities as required to perform duties under the Owner's Agreement with the Authorized Inspection Agency (NCA-5121).

NCA-5200 DUTIES OF INSPECTOR

NCA-5210 GENERAL INSPECTION DUTIES

(a) The Inspector who performs the detailed inspections in compliance with this Section shall witness or otherwise verify all examinations and make all inspections required by this Section. He shall also make any other inspections and witness or verify (including making measurements) any other examinations and additional investigations which, in his judgment, are necessary to ascertain whether the item being inspected has been constructed (NCA-1110, footnotes 1 and 2) in compliance with the rules of this Section. Parts and piping subassemblies shall be in accordance with the accepted documents (NCA-3251). For Division 2, this shall include verification that the items being inspected have been constructed and installed in accordance with the approved Design Drawings and Construction Specifications.

1 Includes Inspectors and Authorized Nuclear Inspector Supervisors.

(b) The duties of the Inspector shall not be interpreted by virtue of these rules to extend to any construction requirements beyond those of this Section which may be set forth in the Design Specification (NCA-3251) or on Design Drawings and Construction Specifications (NCA-3340). However, such requirements shall not result in construction which fails to conform with the requirements of this Section (NCA-3252).

[98]

NCA-5220 CATEGORIES OF INSPECTOR'S DUTIES

The duties of the Inspector shall include but not necessarily be limited to those given in (a) through (m) below:

- (a) verifying the scope of work to be performed [NCA-5230(a)];
- (b) monitoring of the Certificate Holder's Quality Assurance Program including subcontracted activities (NCA-5240);
- (c) reviewing of Certificate Holder's qualification records (NCA-5250);
- (d) verifying materials (NCA-5260);
- (e) witnessing or verifying in-process fabrication, nondestructive examination, and tests (NCA-5270);
- (f) witnessing final pressure tests (NCA-5280);
- (g) reviewing and signing Data Reports and Construction Reports (NCA-5290);
- (h) reviewing drawings and inspecting in accordance with them;
- (i) assuring that Design Reports which are not required by NCA-3551.1 to be certified by a registered Professional Engineer are available;
- (j) assuring that capacity test data has been reviewed and accepted by an ASME designee before signing the pressure and vacuum relief valve Data Report Form NV-1;

- (k) monitoring the Code activities of the Owner [NCA-5242(c)];
 - (l) performing all other duties specifically required in ASME QAI-1-1995, Qualification for Authorized Inspection, as applicable; and
 - (m) verify all preservice examinations have been completed to Section XI edition specified [NCA-3252(c)].
- [98]

NCA-5230 SCOPE OF WORK, DESIGN SPECIFICATIONS, AND DESIGN REPORTS

- (a) The Inspector shall verify that the scope stated in the Certificate includes the work to be performed.

Page 53

(b) The Inspector shall verify that the Design Specification, Design Drawings, Construction Specifications, Construction Reports, Design Reports, Load Capacity Data Sheets, and Certified Design Report Summaries, when required (NCA-3256 and NCA-3550), are on file and that they have been properly certified in accordance with NCA-3255, NCA-3260, NCA-3360, NCA-3380, and NCA-3555.

(c) The Inspector shall not be held responsible for the scope or adequacy of the Design Specifications, for the completeness or accuracy of the Design Report or calculations, for the information reported in the Construction Report, or for the qualification of registered Professional Engineers certifying documents in compliance with the requirements of this Section.

(d) The Inspector shall verify that Design Calculations have been prepared for those components and supports not requiring Design Reports. The Inspector shall not be responsible for the accuracy of the calculations.

NCA-5240 QUALITY ASSURANCE PROGRAMS

NCA-5241 Stipulation of Inspections Prior to Issuance of Process Sheets or Controls

Prior to the issuance of process sheets or controls required by NCA-4134.9, the Certificate Holder shall review them and the applicable drawings with the Inspector, who shall then stipulate the inspections he intends to make in order to fulfill the requirements of NCA-5210.

NCA-5242 Monitoring of Quality Assurance Programs

(a) The Inspector shall monitor the performance of the Certificate Holder for conformity to the requirements of their Quality Assurance Program accepted by the Society. The Inspector shall verify that all changes to the Quality Assurance Manual have been accepted by the Authorized Inspection Agency before they are put into effect.

(b) The Inspector shall assure that the procedures employed in the batching, mixing, conveyance, placing, and curing of structural concrete have been approved under the provisions of the Construction Specification and as specified in Division 2. Certificate Holders shall submit evidence to the Inspector that these requirements have been met.

(c) The Inspector shall monitor the Owner's progress in compiling supporting data needed to complete the ASME Data Report Form N-3.

NCA-5243 Process Control Checklist

The Inspector shall indicate on the Certificate Holder's process sheets or checklist his concurrence that compliance has been attained at each point stipulated by him (NCA-5241).

NCA-5250 QUALIFICATION RECORDS

NCA-5251 Review of Qualification Records

The Inspector shall review the qualification records of the Certificate Holder.

NCA-5252 Structural Concrete Placement

The Inspector shall assure that the procedures employed in the batching, mixing, conveyance, placing, and curing of structural concrete have been approved under the provisions of the Construction Specification and as specified in this Section. The Certificate Holder shall submit evidence to the Inspector that these requirements have been met.

NCA-5253 Welding Procedures

The Inspector shall assure himself that the welding procedures employed in construction have been qualified under the provisions of this Section. The Certificate Holder shall submit evidence to the Inspector that these requirements have been met. When there is a specific reason to question the welding procedure, the Inspector may require requalification as a requirement for the procedure to be used on work subject to his inspection.

NCA-5254 Welders and Welding Operators

The Inspector shall assure himself that all welding is performed by welders or welding operators qualified under the provisions of this Section. The Certificate Holder shall make available to the Inspector a certified copy of the record of performance qualification tests of each welder and welding operator as evidence that these requirements have been met. When there is a specific reason to question the ability of the welder or the welding operator to make welds that meet the requirements of the specification, the Inspector may require requalification before the welder or welding operator is permitted to continue welding on work

Page 54

subject to his inspection. The Inspector shall also assure himself that each welder and welding operator has been assigned an identifying symbol and that such symbols are regularly and consistently applied when required by this Section.

NCA-5255 Examination Procedures

The Inspector shall assure himself that the examination and testing procedures required by this Section have been qualified. When there is a specific reason to question whether the examination or testing procedure requirements are being met, the Inspector may require requalification of the procedure.

NCA-5256 Nondestructive Examination Personnel

The Inspector has the duty to verify the qualification and certification of nondestructive examination personnel employed by the Certificate Holder and has the duty to monitor the nondestructive examination activities and require requalification of any personnel when there is reason to question the performance of that person. In addition, the Inspector shall monitor the Certificate Holder's Quality Assurance Program as it relates to the nondestructive examination activities of Material Manufacturers, Material Suppliers, and NDE subcontractors that the Certificate Holder qualified.

NCA-5260 MATERIALS, PARTS, AND HEAT TREATMENT

NCA-5261 Inspection of Materials for Compliance

The Inspector shall assure himself that all materials used comply with all applicable requirements of this Section. The Certificate Holder shall make available to the Inspector certified reports of the results of all tests performed in accordance with (a) and (b) below:

(a) the material specifications;

(b) the requirements in the applicable materials Articles of this Section, including certified reports of the results of all required tests and examinations performed.

NCA-5262 Dimensional Check

The Inspector shall satisfy himself:

(a) that the item is being constructed within the tolerance required by the Design Specification, Design Drawings, and

Construction Specifications, and this Section;

(b) that head and shell sections conform to the prescribed shape and meet the thickness requirements;

(c) that nozzles and attachments to be welded to the vessel fit properly to the curvature of the vessel surface. If required by the Inspector, the Certificate Holder responsible for the vessel shall make available accurately formed templates for his use.

NCA-5263 Check of Heat Treatment Practice

The Inspector shall satisfy himself that all heat treatment operations required by this Section are correctly performed and that the temperature readings and gradients conform to the requirements.

NCA-5270 EXAMINATIONS AND TESTS

The Inspector shall witness in-process fabrication nondestructive examinations and destructive tests, when feasible; alternatively, he shall check the examination and test records to determine the acceptability of the items involved.

NCA-5280 FINAL TESTS

The Inspector shall witness final hydrostatic, pneumatic, or structural integrity tests required by this Section and examinations performed during such tests by the Certificate Holder. Hydrostatic, pneumatic, or structural integrity tests are not required for core support structures or supports.

[98]

NCA-5290 DATA REPORTS AND CONSTRUCTION REPORTS

(a) The appropriate Data Reports prepared by the Certificate Holder shall be reviewed and signed by the Inspector only after they have been certified by a responsible representative of the Certificate Holder and after he has satisfied himself that all requirements of this Section have been met and that each Data Report certified is a correct record. For Division 2 items, certification by the Designer is also required prior to verification by the Inspector.

(b) The Inspector shall review and separately verify that the information contained in the Construction Report for Division 2 construction is valid and corresponds to the requirements of Division 2 and that the Designer's review and certification of the Construction Report have taken account of all requirements of this Section.

Page 55

(c) The N-3 Data Report (Form NCA-3220) shall be reviewed and signed by the Inspector only after:

(1) it has been certified by the Owner;

(2) the Inspector has reviewed the N-3 Form and verified that the Data Reports referenced on the N-3 Form are on file and that such Data Reports verify Code compliance of all components, parts, appurtenances, supports, and core support structures incorporated into the nuclear power system or that portion of the system covered by the N-3 Form;

(3) the Inspector has verified that required documents for overpressure protection exist and are properly filed for that portion of the system covered by the N-3 Form .

[98]

NCA-5300 RESPONSIBILITIES OF THE AUTHORIZED INSPECTION AGENCY

The responsibilities of the Authorized Inspection Agency shall include but not necessarily be limited to those given in (a) through (k) below.

(a) Maintain a staff of Authorized Nuclear Inspectors and Authorized Nuclear Inspector Supervisors (NCA-5123).

(b) Make agreements with Certificate Holders and Owners for inspection service (NCA-5121 and NCA-8130). Notify the Society whenever such agreements are terminated (NCA-5121).

- (c) Provide for participation in the Society's review of the applicant's Quality Assurance Program (NCA-5125).
- (d) Provide for the review and acceptance of any proposed modifications to Quality Assurance Manuals before they are put into effect (NCA-5125).
- (e) Review and accept the Certificate Holder's method of securing the nameplate to components to which, because of size or other considerations, the nameplate cannot be directly attached [NCA-8220(b)].
- (f) Review and accept the Certificate Holder's alternative method of identification, including the unique method of marking of components to which, because of size or other considerations, nameplates cannot be directly attached [NCA-8220(b)].
- (g) Review and accept the Certificate Holder's alternative method of marking of parts, appurtenances, supports, and piping subassemblies (NCA-8230).
- (h) Review and accept the Certificate Holder's provisions of positive identification and traceability of items from which nameplates are removed [NCA-8240(b)].
- (i) Determine by agreement with the Certificate Holder the sequence for stamping and the completion of the Code Data Report [NCA-8310(c)].
- (j) Review and accept the Certificate Holder's procedure for providing traceability of parts or piping subassemblies which are furnished without stamping (NCA-8332).
- (k) And all other duties specifically required in ASME QAI-1-1995, Qualification for Authorized Inspection as applicable.

July 1, 1998

American Society Of Mechanical Engineers

SEC III NCA-8000

ARTICLE NCA-8000 CERTIFICATES, NAMEPLATES, CODE SYMBOL STAMPING, AND DATA REPORTS

Page 57

NCA-8100 AUTHORIZATION TO PERFORM CODE ACTIVITIES

NCA-8110 GENERAL

Authorization to use the official Code Symbol Stamps or to certify work by other means provided in this Section (see Table NCA-8100-1) will be granted by the Society for a 3 year period pursuant to the provisions set forth in this Subarticle. Authorization to certify Owner's Data Report Forms, N-3, will be granted pursuant to the provisions set forth in this Subarticle.

[98]

NCA-8120 SCOPE OF CERTIFICATES

(a) The Certificate (NCA-8120) will identify the shop or field facility covered and state the scope of activities for which authorization is granted. The Society may, at its discretion, limit or extend the scope of an authorization to any types or classes of items or to a specific location.

(b) A Certificate of Authorization will be issued by the Society to an organization for the use of a Code Symbol Stamp, certifying a data report form, or performing welding or certifying joining.

(c) The installation of items by mechanical means need not be performed by a Certificate Holder. The responsibility for the hydrostatic or pneumatic test of completed components must be assumed by a holder of a Certificate of Authorization and witnessed by the Authorized Nuclear Inspector regardless of the method of assembly. This does not preclude an organization that installs items by mechanical means only from obtaining a Certificate of Authorization.

(d) A Certificate of Accreditation (Corporate) will be issued by the Society to an organization for performing Code activities other than those specified in (b) or (c) above.

(e) A Certificate of Accreditation with an appropriate scope may be issued by the Society to an Organization who has documented a Quality Assurance Program and whose ability to staff, equip, or otherwise implement the described Quality Assurance Program has been evaluated and accepted by the Society. It is not necessary that the Program is or ever was implemented.

(f) The Society may, at any time, make regulations concerning the issuance and use of Certificates and Code Symbol Stamps as it deems appropriate, and all regulations shall become binding upon the holders of a valid Certificate.
[98]

NCA-8130 INSPECTION AGREEMENT REQUIRED

Certificate Holders and Owners shall possess an agreement with an Authorized Inspection Agency¹ to provide inspection and audit services. The agreement with the Authorized Inspection Agency shall be made prior to application for a survey or, in the case of the Owner, an interview. Certificate Holders and Owners shall notify the Society whenever their agreements with an Authorized Inspection Agency are cancelled or changed to another Authorized Inspection Agency.

NCA-8140 QUALITY ASSURANCE PROGRAM REQUIREMENTS

It is a requirement that a Certificate Holder have a Quality Assurance Program (NCA-4000) which has been evaluated and accepted by the Society.

¹ A list of acceptable Authorized Inspection Agencies may be obtained from the Society.

TABLE NCA-8100-1 (CONT'D) CERTIFICATES AND CODE SYMBOL STAMPS ISSUED BY THE SOCIETY FOR CONSTRUCTION OF NUCLEAR POWER PLANTS

Table NCA-8100-1 (CONT'D)

NOTES:

- (1) Items within the containment system, excluding the Class CC and MC vessel and its supports, shall be stamped Class 1 or 2 in accordance with the classification stated in the Design Specification or Construction Specification.
- (2) A Data Report shall be filled out on Form NCS-1 by the Certificate Holder assuming overall responsibility. If this Certificate Holder also performs the fabrication, the Form NCS-1 shall be completed by this Certificate Holder and shall be certified by the Inspector for the core support structure to be stamped with the Code N Symbol and no N-2 Form is required. When a Certificate Holder is responsible for fabrication only, the Form N-2 shall be completed by that Certificate Holder and certified by the Inspector for core support structures, appurtenances, or parts which are to be stamped with the Code NPT Symbol.
- (3) Data Report Form NPP-1 shall be forwarded in duplicate to the N Certificate Holder taking overall responsibility for the piping system and the NA Certificate Holder installing the piping system.
- (4) Data Report Form N-2 for parts shall be forwarded in duplicate to the Certificate Holder of the finished component or support.
- (5) Data Report Form NF-1 for assembled supports shall be forwarded in duplicate to the Certificate Holder who performs installation. A single Data Report may be used for ten completed, assembled supports when each is of the same design and each is identified on the Data Report by serial number.
- (6) A single Data Report may be used for each group of 25 line valves and pumps of the same size and design with inlet piping connection of 4 in. nominal pipe size and smaller when each is identified on the Data Report by an individual serial number.
- (7) Material (NCA-1220) shall be documented by a Certified Material Test Report or a Certificate of Compliance in accordance with NB-NG-2000.
- (8) A multiple number of parts or appurtenances for a single nuclear power plant may be included on the N-2 Data Report, provided the parts or appurtenances are of the same class, size, and design and that the parts or appurtenances are manufactured for the same N Certificate Holder and authorized by the Inspector for stamping on the same day. Each part or appurtenance must be identified on the Data Report by an individual serial number.
- (9) Miscellaneous items as described in NCA-1270 shall be Code symbol stamped and listed on the appropriate Data Report Form when constructed as an "N" or "NPT" item or installed under an "NA" Certificate. When furnished as material, an appropriate Certified Material Test Report or Certificate of Compliance is required in lieu of Data Reports and stamping.

TABLE NCA-8100-1 (CONT'D)

NCA-8150 APPLICATION FOR ACCREDITATION

An Organization desiring a Certificate shall apply to the Society upon forms issued by the Society describing the scope of Code activities to be performed.

NCA-8151 Field Operations

The N, NA, or NPT certificates may be extended to include field operations such as installation, completion, or repair of components, parts, or appurtenances constructed under that authorization. The Society requires that an audit acceptable to the Society be performed at each field site to assure that the Quality Assurance Program described in the Manual is implemented and enforced.

NCA-8152 Shop Assembly

Shop assembly of components to components, or components to appurtenances and piping subassemblies or other items, may be by either NA or N Certificate Holders if such activities are included within the scope of their Certificate.

NCA-8153 Code Activities Prior to Obtaining a Certificate

Code activities performed prior to issuance of a Certificate shall be subject to the acceptance of the Inspector.

NCA-8160 EVALUATION

NCA-8161 Evaluation for a Certificate

(a) Applicants for a new or renewed Certificate for Class 1, 2, 3, CS, CB, CC, or MC construction require a survey of their shop or field facilities. The purpose of the survey is to evaluate the applicant's Quality Assurance Manual and the

implementation of the Quality Assurance Program.

(b) The extent of the survey will be determined by the Society based on a review of the applicant's intended scope of Code activities described in the application. The acceptance by the Society of the Quality Assurance Program shall not be interpreted to mean endorsement of technical capability to perform design work such as system design or stress analysis. Such capability is implied for the specific component involved by the certification of Design Reports (NCA-3360, NCA-3555) by a Registered Professional Engineer.

(c) Authorization to apply a Code Symbol Stamp to an item will be granted only after a survey by the Society has satisfactorily demonstrated the adequacy and implementation of the Quality Assurance Program.

[98]

NCA-8162 Evaluation for an Interim Letter

[98]

NCA-8162 Evaluation for an Owner's Certificate

(a) The Owner, after receipt of notification from the regulatory authority that an application for a construction permit for a specific plant has been docketed, shall obtain an Owner's Certificate (NCA-3230) from the Society for unit(s) docketed concurrently for each nuclear power plant site prior to field installation. In lieu of a survey, the Owner will be interviewed for the Society to verify the Owner's understanding of Code responsibilities (NCA-3220) and to obtain the Owner's agreement to meet the requirements.

(b) The Owner's Certificate (NCA-3230) shall be applicable to nuclear power plant unit(s) docketed concurrently for each site.

[98]

NCA-8170 ISSUANCE

Each Certificate Holder shall have agreed that each Certificate and Code Symbol Stamp (if one is issued) is at all times the property of the Society, that it will be used according to the rules and regulations of this Section, and that the Certificate and Code Symbol Stamp will be promptly returned to the Society upon demand, or when the Certificate Holder discontinues the scope of Code activities covered by his Certificate. The holder of a Code Symbol Stamp shall not permit any other party to use its Certificate or Code Symbol Stamp. The Society reserves the absolute right to cancel or refuse to renew such authorization, returning fees paid for the prorated unexpired term.

NCA-8180 RENEWAL

(a) Not later than 6 months prior to the date of expiration of any Certificate, the Certificate Holder shall apply for a renewal of such authorization and the issuance of a new Certificate.

(b) A Certificate issued for a specific field site, or a Certificate which has been extended to a specific field site activity, is valid for the duration of the contract at the specified site or 3 years, whichever occurs first.

(c) The Owner's Certificate expires when all N-3 Data Reports for the units listed on the Certificate have been completed. Triennially, the Society shall review the status of construction and determine whether the Owner's Certificate shall be renewed.

Page 64

NCA-8200 NAMEPLATES AND STAMPING

NCA-8210 GENERAL REQUIREMENTS

NCA-8211 Nameplates

Each item and installation to which a Code Symbol Stamp is applied shall have a nameplate, except as otherwise permitted by this Subarticle. Marking shall be as required by (a) through (f) below:

- (a) the applicable official Code Symbol Stamp, as shown in Table NCA-8100-1;
- (b) Class of construction;
- (c) the statement "Certified by"
- (d) Certificate Holder's name;
- (e) Certificate Holder's serial number and, if applicable, national board number and/or Canadian registration number;
- (f) marking for line valves shall include the ANSI pressure class rating.

NCA-8212 Stamping

The Code Symbol Stamp shall be stamped on a nameplate attached to an item, except as otherwise permitted by this Subarticle. The arrangement of markings shall be as shown in Fig. NCA-8212-1. The data shall be in characters not less than $\frac{3}{32}$ in. (2.4 mm) high. The selected method shall not result in any harmful contamination or sharp discontinuities. Stamping directly on items, when used, shall be done with blunt-nosed continuous or blunt-nose interrupted dot die stamps.

NCA-8213 Attachment of Nameplates

- (a) The nameplate shall be attached by a method (acceptable to the Designer for Division 2 items) that will not affect the structural integrity of the item.
- (b) If the nameplate is marked before it is attached, the Certificate Holder shall assure that the nameplate with the correct marking has been attached and the Inspector shall verify that this has been done.
- (c) When nameplates are attached with pressure sensitive acrylic adhesive systems, in addition to the requirements of this Article, those of Appendix XXI shall be met.

NCA-8220 NAMEPLATES FOR COMPONENTS

- (a) The markings required by NCA-8210 shall be applied to a separate nameplate attached to the component. In the case of core support structures, the marking shall be applied directly to the support.

	Certified by (Name of Certificate Holder)
Class	(Serial number)

FIG. NCA-8212-1 FORM OF STAMPING

FIG. NCA-8212-1 FORM OF STAMPING

(b) If because of size or other considerations the nameplates cannot be directly attached to the component, the Certificate Holder may secure the nameplate to the component in a manner acceptable to the Authorized Inspection Agency and apply a unique identification mark to the component which will serve to identify the component with the appropriate Data Report. The marking shall be of a visible, permanent type and not detrimental to the component. The type, method, and manner of marking shall be described in the Certificate Holder's Quality Assurance Program or Procedure. The use of this alternative method of identification, including the method of marking, shall be reviewed by and found acceptable to the Authorized Inspection Agency (NCA-5121) prior to implementation by the Certificate Holder.

NCA-8230 NAMEPLATES FOR NPT STAMPED ITEMS

(a) Parts, appurtenances, piping subassemblies, and supports assembled by welding shall have a separate nameplate equivalent to that required for completed components when the size and use of the item will accommodate such a nameplate. When the size or use of the item will not permit the installation of a nameplate, the marking shall consist of suitable identification of the item until it has been incorporated into the finished component or other NPT stamped item. This alternative method of marking shall be reviewed with and found acceptable to the Authorized Inspection Agency before being used by the Certificate Holder.

(b) When the NPT and NA Certificate Holder is not the same organization, the Code Symbol Stamp shown in Table NCA-8100-1 for supports shall be applied to

Page 65

supports assembled by welding which are not furnished integrally with the component. When the NPT and NA Certificate Holder is the same, supports assembled by welding may be furnished without applying the NPT Code Symbol Stamp, provided the Code Symbol Stamp shown in Table NCA-8100-1 for installation of supports is applied to the installation.

(c) In the case of tubular products welded with filler metal, nameplates are not required. The marking shall be applied directly to the material by etching or stamping.

NCA-8240 REMOVED NAMEPLATES

If nameplates secured as noted in NCA-8220 are removed from items which have been installed in a nuclear power plant system, the Certificate Holder responsible for completion of the N-5 Data Report shall verify and document that the required nameplate had been attached to the item. Provisions of positive identification and traceability of the items to a specific location and applicable Data Report shall be included in the Quality Assurance Program or procedure of the Certificate Holder responsible for installation. This alternative shall be reviewed with and found acceptable to the Authorized Inspection Agency (NCA-5121) before being used by the Certificate Holder.

[98]

NCA-8300 CODE SYMBOL STAMPS

[98]

NCA-8310 GENERAL REQUIREMENTS

(a) The Code Symbol Stamp shall be applied by the Certificate Holder only with authorization of the Inspector. In any case, the Code Symbol Stamp shall not be applied until completion of the required examination and testing.

(b) Table NCA-8100-1 provides Code Symbol Stamp requirements as related to type of certificates, scope of work, and class of construction. The class of construction shall be indicated by the applicable number 1, 2, or 3, or letters CS, CB, CC, or MC stamped below and outside the official Code Symbol Stamp.

(c) The completed Code Data Report Form indicates that the Inspector has inspected the item and authorized the application of the Code Symbol Stamp. The sequence for stamping and the completion of the Code Data Report shall be determined by agreement between the Authorized Nuclear Inspector and the Certificate Holder.

[98]

NCA-8320 APPLICATION OF THE N SYMBOL STAMP

NCA-8321 Authorization and Time of Stamping

The N Symbol Stamp shall be applied only with the authorization of the Inspector after the pressure test² requirements have been satisfied and all other examinations, tests, and inspections have been satisfactorily completed.

NCA-8322 Application of the N Symbol Stamp at Field Sites or Other Locations

The N Certificate Holder may apply the N Symbol Stamp to the component in the field, without having the N Certificate of Authorization extended to a field site or other location, under the following provisions:

(a) where the N Certificate Holder elects to substitute the system pressure test [NB/NC/ND-6221(a)] for the component pressure test, the test is conducted under the responsibility of an N or NA Certificate of Authorization issued for that field site and is witnessed and accepted by the N Certificate Holder responsible for the component; or

(b) where the N Certificate Holder elects to subcontract the performance of the component pressure test, the N Certificate Holder shall be responsible for supervising, witnessing, and accepting the pressure test and assuring that the test is controlled in accordance with the suppliers' approved program; or

(c) where the N Certificate Holder elects to perform the component pressure test at a field site or other location, the pressure test shall be controlled in accordance with the N Certificate Holder's Quality Assurance Program.

The completed shop fabrication portion of the Data Report Form, together with the Inspector's own inspections of the component, shall be authority for that field Inspector to witness the test and authorize stamping of the completed component.

² Pressure tests include hydrostatic, pneumatic, and structural integrity tests. Hydrostatic or pneumatic tests are not required for Core Support Structures.

³ In this usage, organization may be the same company at a single site, a multiplant corporation with extended corporate Certificates.

NCA-8330 PARTS AND PIPING SUBASSEMBLIES FURNISHED WITHOUT STAMPING

(a) An organization³ with separate or extended Certificates may manufacture and ship items such as parts

and piping subassemblies without the NPT Symbol Stamp for use at another of its facilities, provided its Quality Assurance Manual includes the provisions of (1) through (3) below.

(1) Requirements for legible and specific identification of each item. Identification shall be permanent and not detrimental to the item. Identification shall be on the item.

(2) Requirements for completing a transmittal form with each shipment of items. The form shall list all items and their corresponding identification number, and shall indicate that the items do not contain the NPT Symbol Stamp. The form shall be signed by the Certificate Holder and the Authorized Nuclear Inspector prior to shipment.

(3) Requirements for receipt of items shipped without the NPT Symbol Stamp. Requirements shall include inspection upon receipt and maintenance and retention of transmittal forms.

(b) Neither an NPT Symbol Stamp, nameplate, Code Data Report, nor transmittal form is required on items manufactured and installed at the same facility by the same Certificate Holder, provided that the Certificate Holder's Quality Assurance Program provides for control of these items through completion of installation.

NCA-8400 DATA REPORTS

NCA-8410 GENERAL REQUIREMENTS

The appropriate Data Report,⁴ as specified in Table NCA-8100-1, shall be filled out by the Certificate Holder or Owner and shall be signed by the Certificate Holder or Owner and the Inspector for each item (except as provided elsewhere in this Article) to be marked with a Code Symbol Stamp.

NCA-8411 Compiling Data Report Records

Data Reports, which are the basis for approval of the C-1, N-3, and N-5 Data Reports, may be compiled in any one of the following methods:

(a) by attaching each Data Report for items which make up that piping system, portion of a piping system, concrete reactor vessel, concrete containment, or nuclear power system to its respective Data Report Form C-1, N-3, or N-5; or

⁴ Samples of the forms referred to in this Subarticle may be found in Appendix V. Copies of these forms may be obtained from the Society.

(b) by assigning each Data Report for items which make up that piping system, portion of a piping system, concrete reactor vessel, concrete containment, or nuclear power system a unique identifying number and listing the numbers on the Data Report Form C-1, N-3, or N-5; or

(c) by attaching a drawing which uniquely identifies each item which makes up that piping system, portion of a piping system, concrete reactor vessel, concrete containment, or nuclear power system to its respective Data Report Form C-1, N-3, or N-5.

NCA-8412 Availability of Data Reports

All Data Reports and referenced supporting material shall be available to the Inspector and enforcement authority having jurisdiction at the location of the nuclear power plant site.

NCA-8420 OWNER'S DATA REPORT

The Owner who has obtained an Owner's Certificate shall be responsible for completing one or more of Form N-3. The Owner shall certify, by signing the form, that each Certificate Holder was the holder of the appropriate Certificate and that components and installation comply with the applicable requirements of this Section. Review of the completed Owner's Data Report Form N-3, including attached Data Reports for all components and installation as required to verify Code Compliance, plus provision of the Overpressure Protection Report or the Overpressure Protection Analysis, when required, shall be the Inspector's authority to sign the Owner's Data Report.

NCA-8430

FILLER METAL

(a) Each piece of tubular products or fittings with filler metal shall be listed on a Data Report Form NM-1. This Data Report shall be completed by the Certificate Holder and signed by the Inspector.

(b) Multiple items may be listed on a single NM-1 Data Report Form, provided they are from the same heat and lot of material.

(c) When tubular products welded with filler metal are used to manufacture fittings, all the fittings made from the NPT stamped tubular product may be identified on one CMTR or NM-1, as applicable, prepared by the fitting manufacturer, which lists all the operations performed by him. The fitting manufacturer shall provide a copy of his CMTR or NM-1, as applicable, and a

Page 67

copy each of the CMTR and the NM-1 Data Report which were supplied with the tubular product.

NCA-8440 DATA REPORTS FOR SUPPORTS

(a) Supports assembled by welding by an NPT Certificate Holder shall be listed on NF-1 Data Report Form, except when the NPT and NA Certificate Holder are the same. When the NPT and NA Certificate Holder are the same, supports may be listed on the N-5 Data Report Form.

(b) Material supplied for supports under provisions of NF-2130 and NF-2150 shall be listed on the N-5 Data Report Form by the NA Certificate Holder.

July 1, 1998

AMERICAN SOCIETY OF MECHANICAL ENGINEERS

SEC III NCA-9000

ARTICLE NCA-9000 GLOSSARY

Page 69

NCA-9100 INTRODUCTION

This Article defines selected terms used in this Section. The definitions in this Glossary shall prevail should a conflict exist with definitions found elsewhere in this Section or other documents referenced in this Section.

[98]

NCA-9200 DEFINITIONS

Approved Supplier. A supplier that has been evaluated and approved by a Material Organization or Certificate Holder in accordance with the requirements of NCA-3800.

Appurtenance. An item intended to be attached to a completed and stamped component which has work performed on it requiring verification by an Inspector.

Audit. A documented evaluation performed to verify, by examination of objective evidence, that those selected elements of a previously approved quality program have been developed, documented, and implemented in accordance with specified requirements. An audit does not include surveillance or inspection for the purpose of process control, or acceptance of material or items.

Authorized Inspection Agency. An organization that is empowered by an enforcement authority to provide inspection personnel and services as required by this Section.

Authorized Nuclear Inspector. An Authorized Nuclear Inspector is an employee of an Authorized Inspection Agency who has qualifications for and has been properly qualified for Division 1 or Division 2.

Authorized Nuclear Inspector Supervisor. An Authorized Nuclear Inspector Supervisor is an employee of an Authorized Inspection Agency who has been assigned by that agency to oversee and direct the work of one or more Authorized Nuclear Inspectors and who has qualifications for and has been properly qualified for Division 1 or Division 2.

Building Structure. The structure whose purpose is to support, house, and protect nuclear power plant components. Rules for construction of building structures are outside the scope of this Section.

Certificate. A Certificate of Authorization, Certificate of Accreditation, Quality System Certificate (Materials), or Owner's Certificate issued by the Society.

Certificate of Accreditation. A document issued by the Society which authorizes the performance of Code activities for a specified time and for a specified scope of activity.

Certificate of Authorization. A document issued by the Society which authorizes the use of an ASME Code Symbol Stamp for a specified time and for a specified scope of activity.

Certificate of Compliance. A written statement attesting that the materials are in accordance with specified requirements.

Certificate Holder. An organization holding a Certificate of Authorization or Certificate of Accreditation issued by the Society.

Certification. The act of verifying and attesting in writing that documents, processes, procedures, items, or the qualifications of personnel are in accordance with specified requirements.

Certified Material Test Report. A document attesting that the material is in accordance with specified requirements, including the actual results of all required chemical analyses, tests, and examinations.

Code Addenda. Additions and revisions to individual sections of the Code published annually.

Code Cases. Documents issued by the Society to clarify the intent of existing Code requirements or to provide alternative rules for construction.

Code Class. The classification, specified by the Owner (or his designee) and included in the Design Specification, which establishes the rules for design and construction of items.

Page 70

Code Editions. Documents issued at 3 year intervals by the Society which include all revisions and additions previously included in Addenda and corrections included in Errata published since the previous Edition.

Code Symbol Stamp. A metallic stamp issued by the Society for use in impressing one of the symbols shown in Table NCA-8100-1.

Compliance. Conforming to the Code, a specification, or a procedure.

Component. A vessel, concrete reactor vessel, concrete containment, pump, pressure relief valve, line valve, storage tank, piping system, or core support structure that is designed, constructed, and stamped in accordance with the rules of this Section.

Component Support. A support for a vessel, pump, or storage tank. A support which is attached to a valve may be classified as a component support when identified in the Design Specification.

Concrete Constituents. Cement, aggregates, admixtures, and water.

Concrete Containment. A composite steel and concrete component that is designed as an integral part of the containment's pressure retaining barrier which retains or controls the release of radioactive or hazardous effluents released from the nuclear power plant equipment which the containment encloses.

Concrete Reactor Vessel. A composite steel and concrete component which functions as a component of the principal pressure containing barrier for the nuclear fuel's primary heat extraction fluid (primary coolant).

Construction (as used in Division I). An all-inclusive term comprising materials, design, fabrication, examination, testing,

inspection, and certification required in the manufacture and installation of an item.

Construction (as used in Division 2). All operations required to build an item in accordance with Design Drawings and the Construction Specification.

Construction Permit. A document issued by the Nuclear Regulatory Commission which authorizes the Owner to construct a nuclear power plant.

Construction Procedure. A written description of construction or fabrication methods the Constructor or Fabricator uses to ensure conformance with the requirements of the Construction Specification, Design Drawings, and this Section.

Construction Report. A report prepared by the Constructor that summarizes activities performed to construct the component in accordance with the Construction Specification, Design Drawings, and the requirements of this Section.

Construction Specification. A document prepared by the Designer that establishes requirements for the construction of a component.

Constructor. The N Certificate Holder in Division 2 responsible for construction [see definition of Construction (as used in Division 2)] and stamping of a component.

Containment System. An item which forms a structure that encloses a nuclear power system or that may be connected to other containment items and which is designed to provide a pressure containing barrier for the primary purpose of containing, within leakage limits, or of channeling, for containment or for controlled disposal, radioactive or hazardous effluents released from the system.

Core Support Structures. Those structures or parts of structures which are designed to provide direct support or restraint of the core (fuel and blanket assemblies) within the reactor pressure vessel.

Corrective Action. Measures taken to rectify conditions adverse to quality, and, where necessary, to preclude repetition.

Data Report. A document which certifies that an item was constructed in accordance with the requirements of this Section.

Data Report Form. The form approved by the Society which is used to record the required Code Data.

Defective Material. Material that does not meet specified requirements.

Design Drawings. Drawings which are prepared to illustrate the structural and mechanical details necessary to comply with the Design Specification and this Section.

Designee. Any organization that performs specified activities at the request of the Owner. The Owner retains the responsibility for the activity performed by the designee.

Design Input Documents. Documents which include those criteria, parameters, bases, or other design requirements upon which detailed final design is based. For this Section, these include the Design Specifications and any other documents referenced by it.

Design Limits. Stress and stress intensity limits applicable to Design Loadings given in the Design Specifications.

Design Loadings. The temperatures, pressures, mechanical loads, and other loading conditions specified in Design Specifications which are the basis for design.

Design Output Documents. Documents defining technical requirements for Section III items such as Certified Design Reports, drawings, calculations, Load Capacity Data Sheets, Certified Design Report Summaries, and Construction Specifications.

Design Pressure. The pressures stated in the Design Specifications for which Design Limits are applicable.

Design Report. The design document which shows that the allowable limits stated in this Section are not exceeded for the loadings specified in the Design Specification.

Design Specification (Division 1). A document prepared by the Owner or Owner's designee which provides a complete basis for construction in accordance with this Section.

Design Specification (Division 2). A document prepared by the Owner or Owner's designee which provides a complete basis for design in accordance with this Section.

Designer. The Division 2 organization responsible for preparation of Design Output Documents.

Discrepancy. A condition outside of an established tolerance or requirement.

Document Control. Those measures established to control the preparation, review, release, issuance, and disposition of documents, such as design calculations, purchase orders, specifications, instructions, procedures, and drawings, including changes thereto, which describe or document activities affecting quality.

Enforcement Authority. A regional or local governing body, such as a state or municipality of the United States or a Canadian province, empowered to enact and enforce boiler and pressure vessel legislation.

Environmental Conditions. Those conditions to which the item is subjected such as radiation, pressure, temperature, humidity, site elevation, wind, and wind direction.

Examination. Specific actions by qualified personnel using qualified procedures to verify that items, fabrication processes, and preservice requirements are in conformance with specified requirements. This term, when used in conjunction with qualification of personnel to perform quality-related activities, shall mean a written examination.

Fabrication. Those actions required to manufacture components, parts, and appurtenances. These actions may include forming, machining, assembling, welding, brazing, heat treating, examination, testing, inspection, and certification. Fabrication does not include design.

Full Penetration Weld. A nonstandard welding term for complete joint penetration.

Hold Point. A designated stopping place during or following a specific activity at which inspection or examination is required before further work can be performed.

Hydrostatic Test. The pressurization of an item to a test pressure using water or other liquid as a testing medium with the required examination prescribed by the Code.

Identification and Verification Program. A documented system for the positive identification of material during storage and handling and verification of the identity of material on the accompanying Certified Material Test Report at the time of shipment.

Inspector. The Authorized Nuclear Inspector as defined in NCA-5122. The term Inspector, as used in this Subsection, is the same as the term Authorized Inspector as used in Division 2.

Installation. Those actions required to place and attach components to their supports and join items of a nuclear power system by welding or mechanical means.

Instructions. Detailed written directions provided to persons or organizations to ensure proper completion of a task.

Intervening Element. An element in the support load path which is constructed to rules other than those of this Section. Intervening elements include, but are not limited to, diesel engines, electric motors, coolers, valve actuators, instrument racks, and access structures.

Item. A product constructed under a Certificate of Authorization (NCA-3120) or material (NCA-1220).

Joining. The act of connecting two or more items to one another, by welding, brazing, bolting, or other mechanical means.

Jurisdictional Boundaries. The physical limits of a Code item which are identified to determine the applicability of Code rules for that item.

Linear Support (Linear-Type Support). A structural element acting under essentially a single component of direct stress. Such elements may also be subjected to shear stresses. Examples of such structural elements are tension and compression struts, beams and columns subjected to bending, trusses, frames, rings, arches, and cables.

Load Capacity Data Sheet. The design document used in lieu of a Design Report when a component support is designed by Load Rating to verify that the requirements of NF-3000 have been met.

Material. For Section III, Division 1, metallic materials manufactured to an SA, SB, SFA, or any other material specification permitted in Section III and which are manufactured, identified, and certified in accordance with the requirements of Section III. For Section III, Division 2, metallic materials, as well as to nonmetallic

Page 72

materials, conforming to the specifications permitted in Section III.

Material Organization (Metallic). An organization accredited by holding Quality System Certificate issued by the Society, or qualified by an accredited Material Organization or Certificate Holder, in accordance with the requirements of Section III, NCA-3800.

Material Specification. A document which establishes the requirements for a material.

Monitor. Observe or check compliance with this Section and the Owner's or Certificate Holder's Quality Assurance Program. This activity is not necessarily documented or required to be continuous.

NA Certificate Holder. The organization which performs those activities required to place and attach components to their support structures and joins items requiring an NA Symbol Stamp.

N Certificate Holder (Division 1). The organization assuming responsibility for Code compliance with respect to material, design, fabrication, installation, examination, testing, inspection, certification, and stamping of items requiring an N Symbol Stamp.

N Certificate Holder (Division 2). The organization assuming responsibility for constructing and stamping of the component, including but not limited to installation of parts in accordance with the Design Drawings and Construction Specification.

Nonconformance. A deficiency in a characteristic, documentation, or procedure that renders an item or activity unacceptable or indeterminate.

Nonmetallic Material. Plastic concrete and grout.

Nonmetallic Material Constituent Supplier. An organization which manufactures, produces, and supplies the concrete constituents for plastic concrete or grout in accordance with the Construction Specification.

Nonmetallic Material Manufacturer. An organization which receives, stores, conveys, and combines the concrete constituents to produce plastic concrete or grout in accordance with the Construction Specification.

NPT Certificate Holder. The organization which fabricates parts, piping subassemblies, supports, or appurtenances requiring an NPT Symbol Stamp.

Nuclear Power Plant. One or more nuclear power systems and containment systems as well as other systems not covered by the rules of this Section.

Nuclear Power System. A system which serves the purpose of producing and controlling an output of thermal energy from nuclear fuel and those associated systems essential to the functions and overall safety of the nuclear power system.

Nuclear Power System Item. An item that is designed to provide a pressure containing barrier or is a pressure retaining member in the system, or an item that is designed as a core support structure or a support.

Owner. The organization legally responsible for the construction and/or operation of a nuclear facility including but not limited to one who has applied for, or has been granted, a construction permit or operating license by the regulatory authority having lawful jurisdiction.

Part. An item which is attached to or becomes a portion of a component or support before completion and stamping of the component or support. Parts have work performed on them requiring verification by an Inspector.

Penetration Assembly. An electrical or mechanical part or appurtenance that permits piping, mechanical devices, or electrical connections to pass through the pressure retaining boundary of a containment vessel.

Performance Assessment. For Section III, a documented evaluation of material supplied by a previously audited and accepted Quality System Program to verify continued compliance with Code requirements.

Piping Subassembly

Piping Subassembly. A section of piping system consisting of fittings and pipes or tubes which are fabricated as subassemblies in a shop or in the field before being installed in a nuclear power system.

Piping Support. A support for piping. A support which is attached to an in-line valve may be classified as a piping support when identified in the Design Specification.

Piping System. A piping system is an assembly of piping, piping supports, components, and, if applicable, component supports of one or more Code Classes, with a defined function as described in the Design Specification for the piping system.

Pneumatic Test. The pressurization of an item to a test pressure using a gas as the testing medium with the required examination prescribed by the Code.

Qualified Procedure. A procedure that has been demonstrated to meet the specified requirements for its intended purpose.

Quality Assurance. As used in this Section, quality assurance comprises all those planned and systematic actions necessary to provide adequate confidence that all items designed and constructed are in accordance with the rules of this Section.

Quality Assurance Manual. A written document which describes a Quality Assurance Program.

Quality Assurance Program. A controlled system of planned and systematic actions required to provide

Page 73

adequate confidence that items designed and constructed are in accordance with the rules of the Code.

Quality System Certificate. A Certificate issued by the Society which permits an organization to perform specified Material Manufacturer or Material Supplier activities in accordance with Code requirements.

Quality System Program. A documented system of actions required to provide adequate confidence that materials conform to the requirements of the material specification and the rules of Section III.

Regulatory Authority. A Federal Government Agency, such as the United States Nuclear Regulatory Commission, empowered to issue and enforce regulations concerning the design, construction, and operation of nuclear power plants.

Repair. The process of physically restoring a nonconformance to a condition such that an item complies with Code requirements.

Rework. Refer to *Repair*.

Service. An activity performed by a subcontractor such as designing, rigging, temporary bolting, and nondestructive examination.

Service Limits. Stress and stress intensity limits applicable to Service Loadings given in the Design Specification.

Shop and Field Drawings. Drawings provided by the Constructor or Fabricator (Division 2) which describe construction, fabrication, and installation details, physical dimensions, arrangements, and any significant engineering features needed to establish conformance to the Design Drawings, Construction Specification, and this Section.

Society. The American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017.

Source Material. For Section III, metallic products used for conversion to or qualification as material by a Certificate Holder or Material Organization.

Special Process. A process, the results of which are highly dependent on the control of the process or skill of the operator, or both.

Standard Support. A support consisting of one or more units usually referred to as catalog items and generally mass produced.

Supplier. Any individual or organization that furnishes materials or services in accordance with a procurement document.

Support. A metal element, excluding an intervening element, which transmits loads between nuclear power plant components and the building structure. A support may be either a component support or a piping support.

Survey. A documented evaluation of an organization's ability to perform Code activities as verified by a determination of the adequacy of the organization's quality program and by a review of the implementation of that program at the location of the

work.

Testing. An element of verification for the determination of the capability of an item to meet specified requirements by subjecting the item to a set of physical, chemical, environmental, or operating conditions.

Traceability. The ability to verify the history, location, or application of an item by means of recorded identification.

Unqualified Source Material. Source material not produced by a Certificate Holder, Material Organization, or approved supplier in accordance with the requirements of Section III, NCA-3800.

Use-as-is. A disposition assigned an item previously identified as nonconforming after reconciling Design Output Documents with the item's as-built condition and verifying that applicable requirements of this Section have been met.

Verification. A review to ensure that activities have been performed and documented in accordance with applicable requirements.

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

Quantity	Unit	Symbol	Other Units or Limitations
Space and Time			
plane angle	radian	rad	degree (decimalized)
length	meter	m	
area	square meter	m ²	
volume	cubic meter	m ³	liter (L) for liquid only (use without prefix other than in milliliter, mL)
time	second	s	minute (min), hour (h), day (d), week, and year
Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section	meter ⁴	m ⁴	
(second moment of area)			
fracture toughness	Pa · $\sqrt{m}$		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
 (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE ADDENDA DISTRIBUTION SCHEDULE

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998

(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering* to invite comments from all interested persons. After the allotted time for public review and final

Page viii

approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in

the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise

Page ix

provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not

"approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NB-1000

ARTICLE NB-1000 INTRODUCTION

Page 1

NB-1100 SCOPE

NB-1110 ASPECTS OF CONSTRUCTION COVERED BY THESE RULES

(a) Subsection NB contains rules for the material, design, fabrication, examination, testing, overpressure relief, marking, stamping, and preparation of reports by the Certificate Holder of items which are intended to conform to the requirements for Class 1 construction.

(b) The rules of Subsection NB cover the requirements for strength and pressure integrity of items, the failure of which would violate the pressure-retaining boundary. The rules cover initial construction requirements, but do not cover deterioration which may occur in service as a result of corrosion, radiation effects, or instability of material. NCA-1130 gives further limitations to the rules of this Subsection.

NB-1120 TEMPERATURE LIMITS

The rules of Subsection NB shall not be used for items which are to be subjected to metal temperatures other than those for which design stress intensity values are given in Section II, Part D, Subpart 1, Tables 2A, 2B, and 4. Above those temperatures, the creep and stress rupture characteristics of materials permitted to be used become significant factors which are not presently covered by the rules of this Subsection. Fatigue design curves and specified methods for fatigue analysis are not applicable above 700°F (371°C) for materials covered by Figs. I-9.1 and I-9.4, and above 800°F (427°C) for materials covered by Figs. I-9.2 and I-9.3.

NB-1130 BOUNDARIES OF JURISDICTION APPLICABLE TO THIS SUBSECTION

NB-1131 Boundary of Components

The Design Specification shall define the boundary of a component to which piping or another component is attached. The boundary shall not be closer to a vessel, tank, pump, or valve than:

- (a) the first circumferential joint in welded connections (the connecting weld shall be considered part of the piping);
- (b) the face of the first flange in bolted connections (the bolts shall be considered part of the piping);
- (c) the first threaded joint in screwed connections.

NB-1132 Boundary Between Components and Attachments

NB-1132.1 Attachments

(a) An *attachment* is an element in contact with or connected to the inside or outside of the pressure-retaining portion of a component.

(b) Attachments may have either a pressure-retaining or a nonpressure-retaining function.

(1) Attachments with a pressure-retaining function include items such as pressure boundary stiffeners, and branch pipe and vessel opening reinforcement.

(2) Attachments with a nonpressure-retaining function include items such as:

(a) valve guides, thermal sleeves, and turning vanes;

(b) core support structures, internal structures, or other permanent structures within the reactor pressure vessel; and

(c) vessel saddles, support and shear lugs, brackets, pipe clamps, trunnions, skirts, and other items in the support load path.

(c) Attachments may also have either a structural or nonstructural function.

Page 4

(1) Attachments with a structural function (structural attachments):

(a) perform a pressure-retaining function;

(b) are core support structures, internal structures, or other permanent structures within the reactor pressure vessel; or

(c) are in the support load path.

(2) Attachments with a nonstructural function (nonstructural attachments):

(a) do not perform a pressure-retaining function;

(b) are not in the support load path.

Nonstructural attachments include items such as name-plates, insulation supports, and locating and lifting lugs.

NB-1132.2 Jurisdictional Boundary.

The jurisdictional boundary between a pressure-retaining component and an attachment defined in the Design Specification shall not be any closer to the pressure-retaining portion of the component than as defined in (a) through (g) below. Figures NB-1132.2-1 through NB-1132.2-3 are provided as an aid in defining the boundary and construction requirements of this Subsection.

(a) Attachments cast or forged with the component and weld buildup on the component surface shall be considered part of the component.

(b) Attachments, welds, and fasteners having a pressure-retaining function shall be considered part of the component.

(c) Except as provided in (d) and (e) below, the boundary between a pressure-retaining component and an attachment not having a pressure-retaining function shall be at the surface of the component.

(d) The first connecting weld of a nonpressure-retaining structural attachment to a component shall be considered part of the component unless the weld is more than $2t$ from the pressure-retaining portion of the component, where t is the nominal thickness of the pressure-retaining material. Beyond $2t$ from the pressure-retaining portion of the component, the first weld shall be considered part of the attachment.

(e) The first connecting weld of a welded nonstructural attachment to a component shall be considered part of the attachment. At or within $2t$ from the pressure-retaining portion of the component, the first connecting weld shall conform to NB-4430.

(f) Mechanical fasteners used to connect a nonpressure-retaining attachment to the component shall be considered part of the attachment.

(g) The boundary may be located further from the pressure-retaining portion of the component than as defined in (a) through (f) above when specified in the Design Specification.

NB-1140 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

Electrical and mechanical penetration assemblies shall be constructed in accordance with the rules for vessels, except that the design and the material performing the electrical conducting and insulating functions need not meet the requirements of this Subsection.

Page 5

Page 6

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

NOTE:

(1) If the attachment is an intervening element [NF-1110(c)], material, design, and connections, as appropriate, are outside Code jurisdiction.

FIG. NB-1132.2-1 ATTACHMENTS IN THE COMPONENT SUPPORT LOAD PATH THAT DO NOT PERFORM A PRESSURE-RETAINING FUNCTION

FIG. NB-1132.2-1 ATTACHMENTS IN THE COMPONENT SUPPORT LOAD PATH THAT DO NOT PERFORM A PRESSURE-RETAINING FUNCTION

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

FIG. NB-1132.2-2 ATTACHMENTS THAT DO NOT PERFORM A PRESSURE-RETAINING FUNCTION AND ARE NOT IN THE COMPONENT SUPPORT LOAD PATH (NONSTRUCTURAL ATTACHMENTS)

GENERAL NOTE:
These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NB-2000

ARTICLE NB-2000 MATERIAL

Page 9

NB-2100 GENERAL REQUIREMENTS FOR MATERIAL

NB-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-1220. The term *Material Organization* is defined in NCA-9000.

(b) The term *pressure-retaining material* as used in this Subsection applies to items such as vessel shells, heads, and nozzles; pipes, tubes, and fittings; valve bodies, bonnets, and disks; pump casings and covers; and bolting which joins pressure-retaining items.

(c) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply.

(1) *plate* - the thickness is the dimension of the short transverse direction

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness)

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness. For axial length > 2 in. (51 mm), the radial thickness is the nominal thickness.

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness

(3) *castings*

(a) Thickness t for fracture toughness testing is defined as the nominal pipe wall thickness of the connecting piping.

(b) Thickness t for heat treatment purposes is defined as the thickness of the pressure-retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure retaining.

NB-2120 PRESSURE-RETAINING MATERIAL

NB-2121 Permitted Material Specifications

(a) Pressure-retaining material shall conform to the requirements of one of the specifications for material given in Section II, Part D, Subpart 1, Tables 2A and 2B, and to all of the requirements of this Article which apply to the product form in which the material is used.

(b) The requirements of this Article do not apply to material for items not associated with the pressure-retaining function of a component, such as shafts, stems, trim, spray nozzles, bearings, bushings, springs, and wear plates, nor to seals, packing, gaskets, valve seats, and ceramic insulating material and special alloys used as seal material in electrical penetration assemblies.

(c) Material made to specifications other than those specified in Section II, Part D, Subpart 1, Tables 2A and 2B may be used for the following applications:

- (1) Safety valve disks and nozzles, when the nozzles are internally contained by the external body structure;
- (2) control valve disks and cages, when the valves function for flow control only;
- (3) line valve disks in valves whose inlet connections are NPS 2 (DN 50) and smaller.

(d) Material for instrument line fittings, 1 in. nominal pipe size (DN 25) and less, may be of material made to specifications other than those listed in Section II, Part D, Subpart 1, Tables 2A and 2B, provided that the fittings are in conformance with the requirements of NB-3671.4 and the material is determined to be adequate for the service conditions by the piping system designer.

(e) Welding and brazing material used in the manufacture of items shall comply with an SFA specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to material used as backing rings or backing strips in welded joints.

Page 16

(f) The requirements of this Article do not apply to hard surfacing or corrosion resistant weld metal overlay which is 10% or less of the thickness of the base material (NB-3122).

NB-2122 Special Requirements Conflicting With Permitted Material Specifications

Special requirements stipulated in this Article shall apply in lieu of the requirements of the material specification wherever the special requirements conflict with the material specification requirements (NCA-3856). Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Required nondestructive examinations shall be performed as specified for each product form in NB-2500. Any examination, repair, test, or treatment required by the material specification or by this Article may be performed by the Material Organization or the Certificate Holder as provided in NB-4121. Any hydrostatic or pneumatic pressure test required by a material specification need not be performed, provided the material is identified as not having been pressure tested and it is subsequently pressure tested in the system in accordance with NB-6114, except where the location of the material in the component or the installation would prevent performing any nondestructive examination required by the material specification to be performed subsequent to the hydrostatic or pneumatic test.

NB-2124 Size Ranges

Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in the rules for construction. In those specifications in which chemical composition or mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range (NCA-3856).

NB-2125 Fabricated Hubbed Flanges

Fabricated hubbed flanges shall be in accordance with the following.

(a) Hubbed flanges may be machined from a hot rolled or forged billet. The axis of the finished flange shall be parallel to the long axis of the original billet. (This is not intended to imply that the axis of the finished flange and the original billet must be concentric.)

(b) Hubbed flanges, except as permitted in (a) above, shall not be machined from plate or bar stock material unless the material has been formed into a ring, and further provided that:

- (1) in a ring formed from plate, the original plate surfaces are parallel to the axis of the finished flange (this is not intended to imply that the original plate surface must be present in the finished flange);
- (2) the joints in the ring are welded butt joints that conform to the requirements of this Section. Thickness to be used to

determine postweld heat treatment and radiography requirements shall be the lesser of t , or $(A - B)/2$, where these symbols are as defined in XI-3130.

(c) The back of the flange and the outer surface of the hub shall be examined by the magnetic particle method or the liquid penetrant method in accordance with NB-2540 to ensure that these surfaces are free from defects.

NB-2126 Integrally Finned Tubes

Integrally finned tubes may be made from tubes that conform to one of the specifications for tubes listed in Section II, Part D, Subpart 1, Tables 2A and 2B, and to all of the special requirements of this Article which apply to that product form. In addition, the following requirements shall apply.

(a) The requirements of NB-2550 shall be met by the tube before finning.

(b) The tubes after finning shall conform to the applicable heat treatment requirements of the basic material specification.

(c) The design stress intensity values, design values of yield strength, and tensile strength values shall be those given in Section II, Part D, Subpart 1, Tables 2A and 2B, and Subpart 2, Tables Y-1, Y-2, and U, respectively, for the tube material from which the finned tube is made.

(d) After finning, each tube shall be subjected to one of the following tests:

(1) an internal pneumatic pressure test at not less than 250 psi without evidence of leakage. The test method, such as immersion of the tube underwater during the test, shall permit visual detection of any leakage.

(2) an individual tube hydrostatic test at 1.25 times the Design Pressure which permits complete examination of the tube for leakage.

Page 17

(e) A visual examination shall be performed after finning. Material having discontinuities, such as laps, seams, or cracks, is unacceptable.

NB-2127 Seal Membrane Material

Seal membrane material (NB-4360) shall conform to the requirements of one of the material specifications listed in Section II, Part D, Subpart 1, Tables 2A and 2B. The requirements of NB-2500 are applicable for the appropriate product form when the material thickness is greater than $\frac{1}{4}$ in. (6 mm).

NB-2128 Bolting Material

(a) Material for bolts and studs shall conform to the requirements of one of the specifications listed in Section II, Part D, Subpart 1, Table 4. Material for nuts shall conform to SA-194 or to the requirements of one of the specifications for nuts or bolting listed in Section II, Part D, Subpart 1, Table 4.

(b) The use of washers is optional. When used, they shall be made of wrought material with mechanical properties compatible with the nuts with which they are to be employed.

NB-2130 CERTIFICATION OF MATERIAL

All material used in construction of components shall be certified as required in NCA-3862 and NCA-3861. Certified Material Test Reports are required for pressure-retaining material except as provided by NCA-3861. A Certificate of Compliance may be provided in lieu of a Certified Material Test Report for all other material. Copies of all Certified Material Test Reports and Certificates of Compliance applicable to material used in a component shall be furnished with the material.

NB-2140 WELDING MATERIAL

For the requirements governing the material to be used for welding, see NB-2400.

NB-2150 MATERIAL IDENTIFICATION

The identification of pressure-retaining material and materials welded thereto shall meet the requirements of NCA-3856. Material for small items shall be controlled during manufacture and installation of a component so that they are identifiable as acceptable material at all times. Welding and brazing material shall be controlled during the repair of material and the manufacture and installation so that they are identifiable as acceptable until the material is actually consumed in the process (NB-4122).

NB-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material. Special consideration shall be given to the influence of elements such as copper and phosphorus on the effects of irradiation on the properties of material (including welding material) in the core belt line region of the reactor vessel. Any special requirement shall be specified in the Design Specifications (NCA-3252 and NB-3124). When so specified, the check analysis shall be made in accordance with the base metal specification and in accordance with NB-2420 for the welding material.

NB-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steels, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the component at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment.

NB-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature by thermocouples in contact with the material or attached to blocks in contact with the material or by calibrated pyrometric instruments. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

Page 18

NB-2190 NONPRESSURE-RETAINING MATERIAL

(a) Material in the component support load path and not performing a pressure-retaining function (see NB-1130) welded to pressure-retaining material shall meet the requirements of NF-2000.

(b) Material not performing a pressure-retaining function and not in the component support load path (nonstructural attachments) welded at or within $2t$ of the pressure-retaining portion of the component need not comply with NB-2000 or NF-2000 provided the requirements of NB-4430 are met.

(c) Structural steel rolled shapes, which are permitted by this Subsection to be furnished with a Certificate of Compliance, may be repaired by welding using the welders, documentation, and examination requirements specified in SA-6.

NB-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

NB-2210 HEAT TREATMENT REQUIREMENTS

NB-2211 Test Coupon Heat Treatment for Ferritic Material¹

Where ferritic steel material is subjected to heat treatment during fabrication or installation of a component, the material used for the tensile and impact test specimens shall be heat treated in the same manner as the component, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. (51 mm) or less are not required to be so heat treated. The Certificate Holder shall provide the Material Organization with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material,

and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

1 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NB-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

NB-2212.1 Cooling Rates.

Where ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing that material shall be cooled at a rate similar to and no faster than the main body of the material except in the case of certain forgings and castings (NB-2223.2 and NB-2226). This rule shall apply to coupons taken directly from the material as well as to separate test coupons representing the material, and one of the general procedures described in NB-2212.2 or one of the specific procedures described in NB-2220 shall be used for each product form.

NB-2212.2 General Procedures.

One of the general procedures stipulated in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with NB-2220. Further specific details of the methods to be used shall be the obligation of the Material Organization and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material which matches the cooling rate of the main body of the product at the region midway between midthickness and the surface ($\frac{1}{4}t$) and no nearer any heat-treated edge than a distance equal to the nominal thickness t being quenched within 25°F and 20 sec at all temperatures after cooling begins from the austenitizing temperature.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material, provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in NB-2220 are used, faster cooling rates at the edges may be compensated for by:

(1) taking the test specimens at least t from a quenched edge, where t equals the material thickness;

(2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed; or

(3) using thermal barriers or insulation at the edge where specimens are to be removed.

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

Page 19

NB-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

NB-2221 General Requirements

The procedure for obtaining test coupons and specimens for quenched and tempered material is related to the product form. Coupon and specimen location and the number of tension test specimens shall be in accordance with the material specifications, except as required by the following paragraphs. References to dimensions signify nominal values.

NB-2222 Plates

NB-2222.1 Number of Tension Test Coupons.

The number of tension test coupons required shall be in accordance with the material specification and with SA-20,

except that from carbon steel plates weighing 42,000 lb and over and alloy steel plates weighing 40,000 lb and over, two tension test coupons shall be taken, one representing the top end of the plate and one representing the bottom end of the plate.

NB-2222.2 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from any heat-treated edge, where t is the nominal thickness of the material.

NB-2222.3 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the component material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with NB-2212.2(b), the dimensions of the coupon shall be not less than $3t \times 3t \times t$, where t is the nominal material thickness.

NB-2223 Forgings

NB-2223.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from any surface and with the midlength of the specimens at least t from any second surface, where t is the maximum heat-treated thickness. A thermal buffer as described in NB-2212.2(c) may be used to achieve these conditions, unless cooling rates applicable to the bulk forgings are simulated as otherwise provided in NB-2212.2.

NB-2223.2 Very Thick and Complex Forgings.

Test coupons for forgings which are both very thick and complex, such as contour nozzles, thick tubesheets, flanges, nozzles, pump and valve bodies, and other complex forgings that are contour shaped or machined to essentially the finished product configuration prior to heat treatment may be removed from prolongations or other stock provided on the product. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat-treated surface, equivalent at least to the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat treatment, and with the midlength of the specimens a minimum of twice this distance from a second heat-treated surface. In any case, the longitudinal axes of the specimens shall not be nearer than $\frac{3}{4}$ in. (19 mm) to any heat-treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. (38 mm) from any second heat-treated surface.

NB-2223.3 Coupons From Separately Produced Test Forgings.

Test coupons representing forgings from one heat and one heat treatment lot may be taken from a separately forged piece under the conditions given in (a) through (e) below.

(a) The separate test forging shall be of the same heat of material and shall be subjected to substantially the same reduction and working as the production forging it represents.

(b) The separate test forging shall be heat treated in the same furnace charge and under the same conditions as the production forging.

(c) The separate test forging shall be of the same nominal thickness as the production forging.

(d) Test coupons for simple forgings shall be taken so that specimens shall have their longitudinal axes at the region midway between midthickness and the surface, and with the midlength of the specimens no nearer any heat-treated edge than a distance equal to the forging thickness, except when the thickness-length ratio of the production forging does not permit, in which case a production forging shall be used as the test forging and the midlength of the specimens shall be at the midlength of the test forging.

NB-2223.4 Test Specimens for Forgings.

When test specimens for forgings are to be taken under the applicable specification, the Inspector shall have the option of witnessing the selection, placing an identifying stamping on them, and witnessing the testing of these specimens.

[98]

NB-2224 Bar and Bolting Material

(a) *Bars*. Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface and with the midlength of the specimens at least t from a heat-treated end, where t is either the bar diameter or thickness.

(b) *Bolting*. For bolting materials, tests shall be made of either full-size bolts or test coupons as required by the base specification. The gage length of the tension specimens and the area under the notch of Charpy specimens shall be at least one diameter or thickness from the heat-treated end.

[98]

NB-2225 Tubular Products and Fittings

NB-2225.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the inside or outside surface and with the midlength of the specimens at least t from a heat-treated end, where t is the nominal wall thickness of the tubular product.

NB-2225.2 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of NB-2223.3 shall be met.

NB-2226 Tensile Test Specimen Location (for Quenched and Tempered Ferritic Steel Castings)

NOTE: Users of this requirement should note that the hardenability of some grades may limit the usable section size.

(a) This section applies only to quenched and tempered ferritic steel castings with a thickness t exceeding 2 in. (51 mm) where t is the thickness of the pressure-retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure-retaining. The order, inquiry, and drawing shall designate what the thickness t is for the casting.

(b) One of the following shall apply.

(1) The longitudinal centering of the thickness of the tension test specimen shall be taken at least $\frac{1}{4}t$ from the t dimension surface. For cylindrical castings, the longitudinal center line of the specimens shall be taken at least $\frac{1}{4}t$ from the outside or inside surface and the gage length at least t from the as-heat-treated end.

(2) Where separately cast test coupons are used, their dimensions shall be not less than $3t \times 3t \times t$ and each specimen cut from it shall meet the requirements of (b)(1) above. The test coupon shall be of the same heat of steel and shall receive substantially the same casting practices as the production casting it represents. (Centrifugal castings may be represented by statically cast coupons.) The test coupon shall be heat treated under the same conditions as the production casting(s). The t dimension of the test coupon shall be the same maximum thickness t as defined in (a) above. Where separate test blocks require reheat treatment, thermal buffers in accordance with (b)(1) above may be used.

(3) Where specimens are to be removed from the body of the casting, a steel, thermal buffer pad $1t \times 1t \times$ at least $3t$ shall be joined to the casting surface by a partial penetration weld completely sealing the buffered surface prior to the heat treatment process. The test specimens shall be removed from the casting in a location adjacent to the center third of the buffer pad. They shall be located at a minimum distance of $\frac{1}{2}$ in. from the buffered surface and $\frac{1}{4}t$ from the other

heat-treated surfaces.

(4) Where specimens are to be removed from the body of the casting, thermal insulation or other thermal barriers shall be used during the heat treatment process adjacent to the casting edge where specimens are to be removed. It shall be demonstrated that the cooling rate of the test specimen is no faster than that of specimens taken by the method described in (b)(1) above. This information shall be included in the test reports.

(5) Where castings are cast or machined to essentially the finished product configuration prior to heat treatment, the test specimens shall be removed from a casting prolongation or other stock on the product at a location below the nearest heat-treated surface indicated on the order. The specimens shall be located with their longitudinal axes a distance below the nearest heat-treated surface equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest heat-treated surface and with their midlength a minimum of twice this distance from a second heat-treated surface. In any case, the longitudinal axes of the test specimens shall be no nearer than $\frac{1}{4}$ in. (6 mm) to a heat-treated surface and the midlength shall be at least $1\frac{1}{2}$ in. (38 mm) from a second heat-treated surface. The component manufacturer shall specify the surfaces of the finished product subjected to high tensile stress in service.

Page 21

NB-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

NB-2310 MATERIAL TO BE IMPACT TESTED

NB-2311 Material for Which Impact Testing Is Required

(a) Pressure-retaining material and material welded thereto shall be impact tested in accordance with the requirements of this Subarticle, except that the material listed in (1) through (7) below is not to be impact tested as a requirement of this Subsection:

(1) material with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) and less where the thicknesses shall be taken as defined in (a) through (e) below:

(a) for pumps, valves, and fittings, use the largest nominal pipe wall thickness of the connecting pipes;

(b) for vessels and tanks, use the nominal thickness of the shell or head, as applicable;

(c) for nozzles or parts welded to vessels, use the lesser of the vessel shell thickness to which the item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections;

(d) for flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub;

(e) for integral fittings used to attach process piping to the containment vessel or a containment vessel nozzle, use the larger nominal thickness of the pipe connections;

(2) bolting, including studs, nuts, and bolts, with a nominal size of 1 in. (25 mm) and less;

(3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;

(4) all thicknesses of material for a pipe, tube, fittings, pumps, and valves with a nominal pipe size 6 in. diameter and smaller;

(5) material for pumps, valves, and fittings with all pipe connections of $\frac{5}{8}$ in. (16 mm) nominal wall thickness and less;

(6) austenitic stainless steels;

(7) nonferrous material.

(b) Drop weight tests are not required for the martensitic high alloy chromium (Series 4XX) steels and precipitation hardening steels listed in Section II, Part D, Subpart 1, Table 2A. The other requirements of NB-2332 apply for these steels. For nominal wall thicknesses greater than $2\frac{1}{2}$ in. (64 mm), the required Charpy V-notch values shall be 40 mils lateral expansion.

NB-2320 IMPACT TEST PROCEDURES

NB-2321 Types of Tests

NB-2321.1 Drop Weight Tests.

The drop weight test, when required, shall be performed in accordance with ASTM E 208-91. Specimen types P-No. 1, P-No. 2, or P-No. 3 may be used. The results, orientation, and location of all tests performed to meet the requirements of NB-2330 shall be reported in the Certified Material Test Report.

NB-2321.2 Charpy V-Notch Tests.

The Charpy V-notch test (C_v), when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of NB-2330 shall be reported in the Certified Material Test Report.

NB-2322 Test Specimens

NB-2322.1 Location of Test Specimens.

Impact test specimens for quenched and tempered material shall be removed from the locations in each product form specified in NB-2220 for tensile test specimens. For material in other heat-treated conditions, impact test specimens shall be removed from the locations specified for tensile test specimens in the material specification. For all material, the number of tests shall be in accordance with NB-2340. For bolting, the C_v impact test specimen shall be taken with the longitudinal axis of the specimen located at least one-half radius or 1 in. below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimens shall be at least one diameter or thickness from the heat-treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NB-2322.2 Orientation of Impact Test Specimens

(a) Specimens for C_v impact tests shall be oriented as follows.

(1) Specimens for forgings, other than bolting and bars used for pressure-retaining parts of vessels, pumps, and valves, shall be oriented in a direction normal to the principal direction in which the material was worked.

Page 22

Specimens are neither required nor prohibited from the thickness direction.

(2) Specimens from material for pipe, tube, and fittings, except for those made from plate and castings, shall be oriented in the axial direction. Specimens from pipe material used for nozzles in vessels shall be oriented in a direction normal to the principal direction in which the material was worked, other than the thickness direction.

(3) Specimens from bolting material and bars shall be oriented in the axial direction.

(4) Specimens for all plate material, including that used for pipe, tube, and fittings, shall be oriented in a direction normal to the principal rolling direction, other than thickness direction.

(5) Specimens for cast material shall have their axes oriented the same as the axes of the tensile specimens (NB-2226).

(6) In cases (1) through (5) above, the notch of the C_v specimen shall be normal to the surface of the material.

(b) Specimens for drop weight tests may have their axes oriented in any direction. The orientation used shall be reported in the Certified Material Test Report.

NB-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS²

NB-2331 Material for Vessels

Pressure-retaining material for vessels, other than bolting, shall be tested as follows.

(a) Establish a reference temperature RT_{NDT} ; this shall be done as follows.

(1) Determine a temperature T_{NDT} that is at or above the nil-ductility transition temperature by drop weight tests.

(2) At a temperature not greater than $T_{NDT} + 60^{\circ}\text{F}$, each specimen of the C_v test (NB-2321.2) shall exhibit at least 35 mils lateral expansion and not less than 50 ft-lb absorbed energy. Retesting in accordance with NB-2350 is permitted. When these requirements are met, T_{NDT} is the reference temperature RT_{NDT} .

In addition to providing a basis for acceptance standards for material, the test data are designated to be used as a basis for establishing inservice operation and for use in fracture prevention evaluation [NB-3211(d) and Appendix G].

(3) In the event that the requirements of (2) above are not met, conduct additional C_v tests in groups of three specimens (NB-2321.2) to determine the temperature T_{Cv} at which they are met. In this case the reference temperature $RT_{NDT} = T_{Cv} - 60^{\circ}\text{F}$. Thus, the reference temperature RT_{NDT} is the higher of T_{NDT} and $(T_{Cv} - 60^{\circ}\text{F})$.

(4) When a C_v test has not been performed at $T_{NDT} + 60^{\circ}\text{F}$, or when the C_v test at $T_{NDT} + 60^{\circ}\text{F}$ does not exhibit a minimum of 50 ft-lb and 35 mils lateral expansion, a temperature representing a minimum of 50 ft-lb and 35 mils lateral expansion may be obtained from a full C_v impact curve developed from the minimum data points of all the C_v tests performed.

(b) Apply the procedures of (a) above to (1), (2), and (3) below:

(1) the base material;

(2) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests in accordance with NB-4330;

(3) the weld metal of NB-2431.

(c) Bars having a width or diameter of 2 in. (51 mm) and less which prohibit obtaining drop weight test specimens shall be tested in accordance with NB-2332.

(d) Some nozzles or appurtenances in vessels, regardless of product form, have insufficient material for obtaining impact tests after heat treatment (except post weld heat treatment). In this case, it is not necessary to perform both the drop weight and transverse C_v impact tests as required by NB-2331(a). Instead, this material may be tested by only using axial C_v specimens. The three C_v specimens so removed shall be tested at a temperature lower than or equal to the lowest service temperature but no higher than the required $RT_{NDT} + 60^{\circ}\text{F}$ for the vessel material to which the nozzle or appurtenance is attached. Each specimen shall exhibit at least 35 mils lateral expansion and not less than 50 ft-lb absorbed energy.

(e) Consideration shall be given to the effects of irradiation (NB-3124) on material toughness properties in the core belt line region of the reactor vessel. The Design Specifications shall include additional requirements, as necessary, to ensure adequate fracture toughness for the service lifetime of the vessel. The toughness properties may be verified in service periodically by a material surveillance program using the methods of ASTM E 185-82 and the material conditions monitored by the inservice inspection requirements of Section XI.

(f) Consideration shall be given to the test temperature requirements of hydrostatic testing of the vessel (NB-6212).

NB-2332 Material for Piping, Pumps, and Valves, Excluding Bolting Material

(a) Pressure-retaining material, other than bolting, with nominal wall thickness $2\frac{1}{2}$ in. (64 mm) and less for piping (pipe and tubes) and material for pumps,

Page 23

valves, and fittings with all pipe connections of nominal wall thickness $2\frac{1}{2}$ in. (64 mm) and less shall be tested as required in (1) and (2) below.

(1) Test three C_v specimens at a temperature lower than or equal to the lowest service temperature as established in the

design specification (NB-3211). All three specimens shall meet the requirements of Table NB-2332(a)-1.

(2) Apply the procedures of (1) above to:

(a) the base material;

(b) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests in accordance with NB-4330; and

(c) the weld metal of NB-2431.

(b) Pressure-retaining material, other than bolting, with nominal wall thickness over $2\frac{1}{2}$ in. (64 mm) for piping (pipe and tubes) and material for pumps, valves, and fittings with any pipe connections of nominal wall thickness greater than $2\frac{1}{2}$ in. (64 mm) shall meet the requirements of NB-2331. The lowest service temperature shall not be lower than $RT_{NDT} + 100^{\circ}\text{F}$ unless a lower temperature is justified by following methods similar to those contained in Appendix G.

NB-2333 Bolting Material

For bolting material, including studs, nuts, and bolts, test three C_v specimens at a temperature no higher than the preload temperature or the lowest service temperature, whichever is less. All three specimens shall meet the requirements of Table NB-2333-1.

NB-2340 NUMBER OF IMPACT TESTS REQUIRED

NB-2341 Plates

One test shall be made from each plate as heat treated. Where plates are furnished in the unheat-treated condition and qualified by heat-treated test specimens, one test shall be made for each plate as-rolled. The term *as-rolled* refers to the plate rolled from a slab or directly from an ingot, not to its heat-treated condition.

NB-2342 Forgings and Castings

(a) Where the weight of an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment lot.

(b) When heat treatment is performed in a continuous type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment

**TABLE NB-2332(a)-1
REQUIRED C_v VALUES FOR PIPING,
PUMPS, AND VALVES**

Nominal Wall Thickness, in. [Note (1)]	Lateral Expansion, mils
$\frac{5}{8}$ or less	No test required
Over $\frac{5}{8}$ to $\frac{3}{4}$, incl.	20
Over $\frac{3}{4}$ to $1\frac{1}{2}$, incl.	25
Over $1\frac{1}{2}$ to $2\frac{1}{2}$, incl.	40

NOTE:

- (1) For pumps, valves, and fittings, use the nominal pipe wall thickness of the connecting piping.

TABLE NB-2332(a)-1 REQUIRED C_v VALUES FOR PIPING, PUMPS, AND VALVES

charge shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2000 lb (907 kg).

TABLE NB-2333-1
REQUIRED C_v VALUES FOR BOLTING MATERIAL

Nominal Diameter, in.	Lateral Expansion, mils	Absorbed Energy, ft-lb
1 or less	No test required	No test required
Over 1 to 4, incl.	25	No requirements
Over 4	25	45

TABLE NB-2333-1 REQUIRED C_v VALUES FOR BOLTING MATERIAL

(c) One test shall be made for each forging or casting of 1000 lb (454 kg) to 10,000 lb (4540 kg) in weight.

(d) As an alternative to (c), a separate test forging or casting may be used to represent forgings or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V-notch and one test for drop weights. The location of drop weight or C_v impact test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg. apart.

(f) As an alternative to (e) for static castings, a separately cast test coupon [NB-2226(b)(2)] may be used; one test shall be made for Charpy V-notch and one test for drop weight.

Page 24

NB-2343 Bars

One test shall be made for each lot of bars with cross-sectional area greater than 1 sq in. (645 mm²), where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed 6000 lb (2720 kg).

NB-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification, but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than 1/4 in. (6 mm); such a lot shall be in a single heat treatment load or in the same continuous run in a continuous furnace controlled within a 50°F (10°C) range and equipped with recording

pyrometers.

NB-2345 Bolting Material

One test shall be made for each lot of material, where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed in weight the following:

1 ³ / ₄ in. diameter and less	1,500 lb
Over 1 ³ / ₄ in. to 2 ¹ / ₂ in. diameter	3,000 lb
Over 2 ¹ / ₂ in. to 5 in. diameter	6,000 lb
Over 5 in. diameter	10,000 lb

NB-2346 Test Definitions

Unless otherwise stated in NB-2341 through NB-2345, the term *one test* is defined to include the combination of the drop weight test and the C_v test when RT_{NDT} is required [NB-2331 and NB-2332(b)] and only the C_v test when determination of RT_{NDT} is not required [NB-2332(a) and NB-2333].

NB-2350 RETESTS

(a) For C_v tests required by NB-2330, one retest at the same temperature may be conducted provided the requirements of (1) through (3) below are met:

(1) the average value of the test results meets the minimum requirements;

(2) not more than one specimen per test is below the minimum requirements;

(3) the specimen not meeting the minimum requirements is not lower than 10 ft-lb (13.6 J) or 5 mils (0.13 mm) below the specified requirements.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retest, both specimens shall meet the minimum requirements.

NB-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency given in (a) and (b) below.

(a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.

(b) C_v impact test machines shall be calibrated and the results recorded to meet the requirements of NCA-3868. The calibrations shall be performed at least once per year using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

NB-2400 WELDING MATERIAL

NB-2410 GENERAL REQUIREMENTS

(a) All welding material used in the construction and repair of components or material, except welding material used for cladding or hard surfacing, shall conform to the requirements of the welding material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in NB-2150.

(b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable.

(1) welding process;

(2) SFA Specification and classification;

- (3) other identification if no SFA Specification applies;
 - (4) minimum tensile strength [NB-2431.1(e)] in the as-welded or heat-treated condition or both [NB-2431.1(c)];
 - (5) drop weight test for material as-welded or heat treated, or both (NB-2332);
-

Page 25

- (6) Charpy V-notch test for material as-welded or heat treated, or both (NB-2331); the test temperature and the lateral expansion or the absorbed energy shall be provided;
- (7) the preheat and interpass temperatures to be used during welding of the test coupon [NB-2431.1(c)];
- (8) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [NB-2431.1(c)];
- (9) elements for which chemical analysis is required per the SFA Specification or Welding Procedure Specification and NB-2432;
- (10) minimum delta ferrite (NB-2433).

NB-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electrogas welding) processes (Section IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes, and dry blend of supplementary powdered filler metal, and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electrosag flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by NB-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities to which the liquid binders may be added to produce a number of wet mixes [(c) below].

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch or dry blend [(a) and (b) above, respectively], and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled tube, wire, or strip and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding material is coded for identification and traceable to the production period, the shift, line, and the analysis range of both the mix and the rod, tube, or strip used to make the electrode.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with a maximum of one splice per coil that has been chemically analyzed to ensure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed, except that those coils which are splice free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to ensure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a *heat* may be defined as either the material produced from the same melt of metal or the material produced from one type and size of wire when produced in a continuous period [not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg)] from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

Page 26

(2) Carbon, manganese, silicon, and other intentionally added elements shall be identified to ensure that the material conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A *lot of submerged arc or electroslag flux* is defined as the quantity of flux produced from the same combination of raw materials under one production schedule.

(h) A *dry blend of supplementary powdered filler metal* is defined as one or more mixes of material produced in a continuous period, not to exceed 24 hr and not to exceed 20,000 lb (9070 kg) from chemically controlled mixes of powdered filler metal, provided each container of powdered metal is coded for identification and traceable to the production period, the shift, and the mixing vessel. A *chemically controlled mix of powdered filler metal* is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

NB-2430 WELD METAL TESTS

NB-2431 Mechanical Properties Test

Tensile and impact tests shall be made, in accordance with this paragraph, of welding materials which are used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below:

(a) austenitic stainless steel and nonferrous welding material used to join the listed P-Numbers;

(b) consumable inserts (backing filler material);

(c) welding material used for GTAW root deposits with a maximum of two layers;

(d) welding material to be used for the welding of base material exempted from impact testing by NB-2311 shall likewise be exempted from the impact testing required by NB-2330 and this paragraph.

NB-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below, using each process with which the weld material will be used in production welding.

(a) Test coupons shall be of sufficient size and thickness such that the test specimens required herein can be removed.

(b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such a manner as to eliminate substantially the influence of the base material on the results of the tests. Weld metal to be used with the

electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure Specifications (WPS) for production welding, Section IX, QW-2a. The base material shall conform to the requirements of Section IX, QW-403.1 or QW-403.4, as applicable.

(c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures that will be used in production welding. Coupons shall be tested in the as-welded condition, or they shall be tested in the applicable postweld heat-treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time¹ shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the component. In addition, weld coupons for weld metal to be used with the electroslag process, which are tested in the as-welded condition or following a postweld heat treatment within the holding temperature ranges of Tables NB-4622.1-1 or NB-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment, which will include heating the coupon to a temperature above the Holding Temperature Range of Table NB-4622.1-1 for the type of material being tested, shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.

(d) Regardless of the welding process or welding material being tested, the tensile specimens, and the C_v impact specimens where required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. Drop weight impact test specimens, where required, shall be oriented so that the longitudinal axis is transverse to the weld with the notch in the weld face or in a plane parallel to the weld face. For impact

Page 27

specimen preparation and testing, the applicable parts of NB-2321.1 and NB-2321.2 shall apply. The longitudinal axis of the specimen shall be at a minimum depth of $\frac{1}{4}t$ from a surface, where t is the thickness of the test weld.

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. When base materials of different specifications are to be welded, the tensile strength requirements shall conform to the specified minimum tensile strength requirements of either of the base material specifications.

(f) Impact specimens of the weld metal shall be tested where impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the parts of NB-2331(a) or NB-2332 applicable to the base material. Where different requirements exist for the two base materials, the weld metal may conform to either of the two requirements.

NB-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in NB-2431.1, tensile and impact tests may be made in accordance with this subparagraph where they are required for mild and low alloy steel covered electrodes; the material combinations to require weld material testing, as listed in NB-2431, shall apply for this Standard Test Requirements option. The limitations and testing under this Standard Test option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in Specifications SFA-5.1 or SFA-5.5.

(b) The test assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of C_v specimens and the drop weight test specimens required by NB-2331(a) or NB-2332, where applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA Specification for the classification of electrode being tested. Coupons shall be tested in the as-welded condition and also in the postweld heat-treated condition. The PWHT temperatures shall be in accordance with Table NB-4622.1-1 for the applicable P-Number equivalent. The time at PWHT temperature shall be 8 hr. (This qualifies PWHT of 10 hr or less.) When the PWHT of the production weld exceeds 10 hr, or the PWHT temperature is other than that required above, the general test of NB-2431.1 shall be used.

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of

**TABLE NB-2432.1-1
SAMPLING OF WELDING MATERIALS FOR
CHEMICAL ANALYSIS**

	GTAW/PAW	GMAW	All Other Processes
A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE NB-2432.1-1 SAMPLING OF WELDING MATERIALS FOR CHEMICAL ANALYSIS

SFA-5.1 or SFA-5.5, as applicable. Drop weight impact test specimens, where required, shall be located and oriented as specified in NB-2431.1(d).

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirement of the SFA Specification for the applicable electrode classification.

(f) The requirements of NB-2431.1(f) shall be applicable to the impact testing of this option.

NB-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with NB-2420 and as required by the following subparagraphs.

NB-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this subparagraph and Table NB-2432.1-1, and the results shall conform to NB-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to

be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the

welding material specification specifies percentage composition limits for analysis, it shall state that the specified limits apply for the filler metal analysis, the undiluted weld deposit analysis, or *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in the applicable SFA Specification. Where a weld deposit method is not provided by the SFA specification, the sample shall be removed from a weld pad, groove, or other test weld³ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specifications that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the mechanical properties test coupon. Where a chemical analysis is required for a welding material which does not have a mechanical properties test requirement, a chemical analysis test coupon shall be prepared as required by NB-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of NB-2431.1(c) do not apply.

(d) The alternative method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion resistant overlay cladding shall require a test weld made in accordance with the essential variables of the Welding Procedure Specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform with QW-214.3 for the minimum thickness for which the welding procedure specification is qualified.

NB-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a) through (c) below.

³ The methods given in the Appendix of SFA-5.9, Specification for Corrosion Resisting Chromium and Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

TABLE NB-2432.2(a)-1 CHEMICAL ANALYSIS FOR REACTOR VESSEL WELDING MATERIAL

Carbon and low alloy materials	C, Cr, Mo, Ni, Mn, Si, P, S, V, Cu
Chromium and Cr–Ni stainless material	C, Cr, Mo, Ni, Mn, Si, P, S, V, Cb + Ta, Ti, Cu

TABLE NB-2432.2(a)-1 CHEMICAL ANALYSIS FOR REACTOR VESSEL WELDING MATERIAL

TABLE NB-2432.2(a)-2 CHEMICAL ANALYSIS FOR WELDING MATERIAL FOR OTHER THAN REACTOR VESSEL WELDS

Chromium–Nickel stainless steels	C, Cr, Mo, Ni, Mn, Si, Cb + Ta
---	---------------------------------------

TABLE NB-2432.2(a)-2 CHEMICAL ANALYSIS FOR WELDING MATERIAL FOR OTHER THAN REACTOR VESSEL WELDS

(a)(1) All welding material to be used in the reactor vessel shall be analyzed for the elements listed in Table NB-2432.2(a)-1.

(2) All welding material of ferrous alloys A-No. 8 and A-No. 9 (Section IX, QW-442) to be used in other components shall be analyzed for the elements listed in Table NB-2432.2(a)-2 and for any other elements specified in the welding material specification referenced by the WPS or in the WPS.

(3) All other welding material shall be analyzed for the elements specified in either the welding material specification referenced by the WPS or in the WPS.

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a

modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements, these composition limits of the welding procedure specification shall apply for acceptability.

(c) The results of the chemical analysis shall be reported in accordance with NCA-3867. Elements listed in Table NB-2432.2(a)-1 or Table NB-2432.2(a)-2 but not specified in the welding material specification or WPS shall be reported for information only.

NB-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta

Page 29

ferrite determinations are not required for SFA-5.9 and SFA-5.4, Type 16-8-2, or A-No. 8 weld filler metal to be used for weld metal cladding.

NB-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of NB-2432 in conjunction with Fig. NB-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS-A4.2-91.

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NB-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number (FN).

NB-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN. The results of the delta ferrite determination shall be included in the Certified Material Test Report of NB-2130 or NB-4120.

NB-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

NB-2500 EXAMINATION AND REPAIR OF PRESSURE-RETAINING MATERIAL

NB-2510 EXAMINATION OF PRESSURE-RETAINING MATERIAL

(a) Pressure-retaining material and material welded thereto shall be examined by nondestructive methods applicable to the material and product form as required by the rules of this Subarticle, except for pumps and valves with inlet piping connections 2 in. nominal pipe size (DN 50) and less. Seamless pipe, tubes, and fittings, 1 in. nominal pipe size (DN 25) and less, need not be examined by the rules of this Subarticle. The 1 in. size exemption does not apply to heat exchanger tubing.

(b) For forged and cast pumps and valves with inlet piping connections over 2 in. (DN 50), up to and including 4 in. nominal pipe size (DN 100), magnetic particle or liquid penetrant examinations may be performed in lieu of volumetric examination, except that the welding ends for cast pumps and valves shall be radiographed for a minimum distance of t (when t is the design section thickness of the weld) from the final welding end.

(c) The requirements of this Subarticle for repair by welding, including examination of the repair welds, shall be met wherever repair welds are made to pressure-retaining material and material welded thereto. The exceptions in (a) and (b) above do not apply to repair welds.

NB-2520 EXAMINATION AFTER QUENCHING AND TEMPERING

Ferritic steel products that have their properties enhanced by quenching and tempering shall be examined by the methods specified in this Subarticle for each product form after the quenching and tempering phase of the heat treatment.

NB-2530 EXAMINATION AND REPAIR OF PLATE

NB-2531 Required Examination

All plates 2 in. (51 mm) nominal thickness and less used for piping, pumps, and valves shall be examined by the angle beam ultrasonic method in accordance with NB-2532.2. All plates for vessels and all plates greater than 2 in. (51 mm) thickness shall be examined by the straight beam ultrasonic method in accordance with NB-2532.1.

NB-2532 Examination Procedures

NB-2532.1 Straight Beam Examination.

The requirements for straight beam examination shall be in accordance with SA-578, Specification for Straight Beam Wave Ultrasonic Testing and Inspection of Plain and Clad Steel Plates for Special Applications, as shown in Section V, except that the extent of examination and the acceptance standards to be applied are given in (a) and (b) below.

(a) Extent of Examination. One hundred percent of one major plate surface shall be covered by moving the search unit in parallel paths with not less than a 10% overlap.

(b) Acceptance Standards

(1) Any area where one or more imperfections produce a continuous total loss of back reflection accompanied

Page 30

Page 31

by continuous indications on the same plane that cannot be encompassed within a circle whose diameter is 3 in. (76 mm) or one-half of the plate thickness, whichever is greater, is unacceptable.

GENERAL NOTES:

- (a) The actual nitrogen content is preferred. If this is not available, the following applicable nitrogen value shall be used:
 (1) GMAW welds - 0.08%, except that when self shielding flux cored electrodes are used - 0.12%.
 (2) Welds made using other processes - 0.06%.
- (b) This diagram is identical to the WRC-1992 Diagram, except that the solidification mode lines have been removed for ease of use.

FIG. NB-2433.1-1 WELD METAL DELTA FERRITE CONTENT

FIG. NB-2433.1-1 WELD METAL DELTA FERRITE CONTENT

(2) In addition, two or more imperfections smaller than described in (1) above shall be unacceptable unless separated by a minimum distance equal to the greatest diameter of the larger imperfection, or unless they may be collectively encompassed by the circle described in (1) above.

NB-2532.2 Angle Beam Examination.

The requirements for angle beam examination shall be in accordance with SA-577, Specification for Ultrasonic Beam Wave Inspection of Steel Plates, as shown in Section V and supplemented by (a) and (b) below. The calibration notch, extent of examination, and acceptance standards to be applied are given in (a) through (c) below.

(a) *Calibration.* Angle beam examination shall be calibrated from a notch.

(b) *Extent of Examination.* One hundred percent of one major plate surface shall be covered by moving the search unit in parallel paths with not less than 10% overlap.

(c) *Acceptance Standards.* Material which shows one or more imperfections which produce indications exceeding in amplitude the indication from the calibration notch is unacceptable unless additional exploration by the straight beam method shows the imperfections are laminar in nature and are acceptable in accordance with NB-2532.1(b).

NB-2537 Time of Examination

Acceptance examinations shall be performed at the time of manufacture as required in (a) through (c) below.

(a) *Ultrasonic examination* shall be performed after rolling to size and after heat treatment, except for postweld heat treatment.

(b) *Radiographic examination* of repair welds, when required, may be performed prior to any required postweld heat treatment.

(c) *Magnetic particle or liquid penetrant examination* of repair welds shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment of P-No.1 material 2 in. and less nominal thickness.

NB-2538 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (d) below are met.

(a) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(b) After defect elimination, the area is examined by the magnetic particle method in accordance with NB-2545 or the liquid penetrant method in accordance with NB-2546 to ensure that the defect has been removed or reduced to an imperfection of acceptable size.

(c) Areas ground to remove oxide scale or other mechanically caused impressions for appearance or to facilitate proper ultrasonic testing need not be examined by the magnetic particle or liquid penetrant test method.

(d) When the elimination of the defect reduces the thickness of the section below the minimum required to satisfy NB-3000, the product shall be repaired in accordance with NB-2539.

NB-2539 Repair by Welding

The Material Organization may repair by welding material from which defects have been removed, provided the depth of the repair cavity does not exceed one-third the nominal thickness and the requirements of the following subparagraphs are met. Prior approval of the Certificate Holder shall be obtained for the repair of plates to be used in the manufacture of vessels.

NB-2539.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of acceptable size by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (NB-4211.1).

NB-2539.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with NB-4000 and Section

IX.

NB-2539.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NB-2539.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (NB-2545) or by the liquid penetrant method (NB-2546). In addition, when the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, the repair weld shall be radiographed after repair in accordance with NB-5110 and to the acceptance standards of NB-5320. The penetrameter and the acceptance standards for radiographic examination

Page 32

of repair welds shall be based on the section thickness at the repair area.

NB-2539.5 Heat Treatment After Repairs.

The product shall be heat treated after repair in accordance with the heat treatment requirements of NB-4620.

NB-2539.6 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film.

NB-2539.7 Repair of Cladding by Welding.

The Material Organization may repair defects in cladding by welding, provided the requirements of (a) through (d) below are met.

(a) Qualification of Welding Procedures and Welders. The welding procedure and the welders or welding operators shall be qualified in accordance with NB-4000 and with Section IX.

(b) Defect Removal and Examination of Cavity. The defect shall be removed, and the cavity prepared for repair shall be examined by the liquid penetrant method (NB-2546).

(c) Examination of Repaired Areas. The repaired area shall be examined by a liquid penetrant method (NB-2546).

(d) Report of Repairs. Each defect repair shall be described in the Certified Material Test Report for each piece, including a chart which shows the location and size of the repair, the welding material identification, welding procedure, heat treatment, and examination results.

NB-2540 EXAMINATION AND REPAIR OF FORGINGS AND BARS

NB-2541 Required Examinations

(a) Forgings and bars shall be examined by the ultrasonic method in accordance with NB-2542, except forgings or sections of forgings which have coarse grains, or configurations which do not yield meaningful examination results by ultrasonic methods, shall be examined by radiographic methods in accordance with Section V, Article 2, using the acceptance standards of NB-5320. In addition, all external surfaces and accessible internal surfaces shall be examined by a magnetic particle method (NB-2545) or a liquid penetrant method (NB-2546).

(b) Forged flanges and fittings, such as elbows, tees, and couplings, shall be examined in accordance with the requirements of NB-2550.

(c) Bar material used for bolting shall be examined in accordance with NB-2580.

(d) Forgings and forged or rolled bars which are to be bored to form tubular products or fittings shall be examined in

accordance with the requirements of NB-2550 after boring.

(e) Forgings and forged or rolled bars which will subsequently be bored to form pump and valve parts shall be examined in accordance with NB-2541 after boring.

NB-2542 Ultrasonic Examination

NB-2542.1 Examination Procedure.

All forgings in the rough-forged or finished condition, and bars, shall be examined in accordance with Article 5 of Section V and the following supplemental requirements. The techniques of (a) through (d) below are required, as applicable.

(a) Forgings may be examined by the use of alternative ultrasonic methods which utilize distance amplitude corrections, provided the acceptance standards are shown to be equivalent to those listed in NB-2542.2.

(b) Cylindrical section bars shall be scanned from the entire external circumference.

(c) Noncylindrical section bars shall be scanned in two perpendicular directions to the maximum extent possible (through each pair of parallel sides).

(d) Bar products do not require recording and reporting of indications smaller than the acceptance standard, except when so specified for specialized applications.

NB-2542.2 Acceptance Standards

(a) Straight Beam General Rule. A forging shall be unacceptable if the results of straight beam examinations show one or more reflectors which produce indications accompanied by a complete loss of back reflection not associated with or attributable to geometric configurations. Complete loss of back reflection is assumed when the back reflection falls below 5% of full calibration screen height.

(b) Straight Beam Special Rule for Vessel Shell Sections

(1) A ring forging made to fine grain melting practice and used for vessel shell sections shall be unacceptable if the results of the straight beam radial examination show one or more reflectors producing a

Page 33

continuous complete loss of back reflection accompanied by continuous indications on the same plane that cannot be encompassed with a circle whose diameter is 3 in. or one-half of the wall thickness, whichever is greater.

(2) In addition, two or more reflectors smaller than described in (1) above shall be unacceptable unless separated by a minimum distance equal to the greatest diameter of the larger reflector or unless they may be collectively encompassed by the circle described in (1) above.

(c) Angle Beam Rule. A forging shall be unacceptable if the results of angle beam examinations show one or more reflectors which produce indications exceeding in amplitude the indication from the appropriate calibration notches.

NB-2545 Magnetic Particle Examination

NB-2545.1 Examination Procedure.

The procedure for magnetic particle examination shall be in accordance with the methods of Article 7, Section V.

NB-2545.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication in excess of the NB-2545.3 acceptance standards, which is believed to be nonrelevant, shall be

reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NB-2545.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NB-2546 Liquid Penetrant Examination

NB-2546.1 Examination Procedure.

The procedure for liquid penetrant examination shall be in accordance with the methods of Section V, Article 6.

NB-2546.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities, such as may occur from machining marks, surface conditions, or an incomplete bond between base metal and cladding, may produce similar indications which are not relevant.

(b) Any indication in excess of the NB-2546.3 acceptance standards, which is believed to be nonrelevant, shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation, which would mask defects, are unacceptable.

(c) Relevant indications are indications which result from imperfections. *Linear indications* are indications in which the length is more than three times the width. *Rounded indications* are indications which are circular or elliptical with the length equal to or less than three times the width.

NB-2546.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and

greater than $\frac{1}{16}$ in. (4.8 mm) for thicknesses $\frac{1}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NB-2547 Time of Examination

Acceptance examinations, including those for repair welds, shall be performed at the time of manufacture as required in (a) through (e) below.

(a) Ultrasonic examination may be performed at any time after forging [NB-2541(d)], and the maximum practical volume, including weld repairs, if required, shall be examined after final heat treatment, excluding postweld heat treatment.

(b) Radiographic examination of repair welds, if required, may be performed prior to any required postweld heat treatment.

(c) Magnetic particle or liquid penetrant examination shall be performed in the finished condition, except repair welds of P-No. 1 material, 2 in. (51 mm) nominal thickness and less, may be examined prior to postweld heat treatment.

(d) Forgings and rolled bars which are to be bored or turned to form tubular parts or fittings shall be examined after boring or turning, except for threading.

(e) Forgings and forged or rolled bars which will subsequently be bored or turned to form pump and valve parts shall be examined after boring or turning, except for threading.

NB-2548 Elimination of Surface Defects

Elimination of surface defects shall be made in accordance with NB-2538.

NB-2549 Repair by Welding

Repair by welding shall be in accordance with NB-2539, except that:

(a) the depth of repair that is permitted is not limited; and

(b) for ferritic steel forgings, the completed repair may be examined by the ultrasonic method in accordance with the requirements of NB-2542 in lieu of radiography.

NB-2550 EXAMINATION AND REPAIR OF SEAMLESS AND WELDED (WITHOUT FILLER METAL) TUBULAR PRODUCTS AND FITTINGS

NB-2551 Required Examination

In addition to the requirements of the material specification and of this Article, seamless and welded (without filler metal) tubular products (including pipe flanges and fittings machined from forgings and bars) shall comply with the following.

(a) Wrought seamless and welded (without filler metal) pipe and tubing shall be examined over the entire volume⁴ of the material in accordance with (1), (2), (3), or (4), as follows. Tubular products may require both outside and inside surface conditioning prior to examination.

(1) Pipe and Tubing

(a) Pipe and tubing smaller than $2\frac{1}{2}$ in. (64 mm) O.D. shall be examined by the ultrasonic method in accordance with NB-2552(a)(1) in two opposite circumferential directions⁵ and by the eddy current method in accordance with NB-2554, provided the product is limited to sizes, materials, and thicknesses for which meaningful results can be obtained by eddy current examination as evidenced by detection of required standards.

(b) As an alternative to the eddy current examination or when the eddy current examination does not yield meaningful results, an axial scan ultrasonic examination in two opposite axial directions,⁵ in accordance with NB-2552(a)(2), shall be made.

(2) Pipe and tubing $2\frac{1}{2}$ in. (64 mm) O.D. and larger shall be examined by the ultrasonic method in accordance with NB-2552(a)(1) in two opposite circumferential directions, and in accordance with NB-2552(a)(2) in two opposite axial directions. Alternatively, for welded without filler metal pipe larger than $6\frac{3}{4}$ in. (171 mm) O.D., the plate shall be examined by the ultrasonic method in accordance with NB-2530 prior to forming and the weld shall be examined by the radiographic method in accordance with NB-2553. Radiographic examination of welds, including repair welds, shall be performed after final rolling and forming and may be performed prior to any required postweld heat treatment.

4 The volumetric examinations required by this paragraph need only be conducted from one surface.

5 The direction of ultrasonic examinations referenced is the direction of sound propagation.

Page 35

(3) Copper-nickel alloy and nickel alloy seamless pipe and tubing shall be examined as follows.

(a) Except as provided in (d) below, each pipe and tube, all sizes shall be ultrasonically examined in accordance with NB-2552(a)(1) in two opposite circumferential directions.

(b) Except as provided in (d) below, pipe and tubing smaller than $2\frac{1}{2}$ in. (64 mm) O.D. shall be examined by the eddy current method in accordance with NB-2554 if meaningful indications can be obtained from the reference specimen notches. If meaningful indications cannot be obtained from the reference specimen, an axial scan ultrasonic examination in two opposite axial directions, in accordance with NB-2552(a)(2), shall be made.

(c) Except as provided in (d) below, pipe and tubing $2\frac{1}{2}$ in. (64 mm) O.D. and larger shall be examined by an axial scan ultrasonic examination in two opposite axial directions in accordance with NB-2552(a)(2).

(d) For pipe and tubing which is specified to be coarse grain structure, radiographic examination in accordance with NB-2553 may be performed in lieu of ultrasonic examination.

(4) Tubing used in steam generator fabrication shall be examined as follows:

(a) each tube shall be ultrasonically examined in accordance with NB-2552(a)(1) in two opposite circumferential directions, and

(b) by eddy current in accordance with NB-2554 if meaningful indications can be obtained from the reference specimen notches. If meaningful results cannot be obtained from the reference specimen, an axial scan ultrasonic examination in two opposite axial directions, in accordance with NB-2552(a)(2), shall be made.

(b) Wrought seamless and welded without filler metal fittings (including pipe flanges and fittings machined from forgings and bars) shall be examined in accordance with the material specification, and in addition by the magnetic particle method in accordance with NB-2555, or the liquid penetrant method in accordance with NB-2556 on all external surfaces and all accessible internal surfaces (excluding bolt holes and threads). Additionally, for fittings over 6 in. (152 mm) nominal size, the entire volume shall be examined by the ultrasonic method, if feasible, in accordance with NB-2552, or the radiographic method in accordance with NB-2553. Alternatively, the plate shall be examined by the ultrasonic method in accordance with NB-2530 prior to forming and the weld shall be examined by the radiographic method in accordance with NB-2553. Radiographic examination of welds, including repair welds, shall be performed after final rolling and forming, and may be performed prior to any required postweld heat treatment.

(c) Tubular products used for vessel nozzles shall be examined over the entire volume of material by either the ultrasonic method in two opposite circumferential directions in accordance with NB-2552(b) or the radiographic method in accordance with NB-2553, and shall be examined on all external and all accessible internal surfaces by either the magnetic particle method in accordance with NB-2555 or the liquid penetrant method in accordance with NB-2556.

NB-2552 Ultrasonic Examination⁴

(a) *Examination Procedure for Pipe and Tubing.* Independent channels or instruments shall be employed for circumferential and axial scans.

(1) *Circumferential Direction.* The procedure for ultrasonic examination of pipe and tubing in the circumferential direction shall be in accordance with SE-213. The procedure shall provide a sensitivity which will consistently detect defects that produce indications equal to, or greater than, the indications produced by the standard defects specified in (c).

(2) *Axial Direction.* When required by NB-2551, the ultrasonic examination of pipe and tubing shall include angle beam scanning in the axial direction. The procedure for the axial scans shall be in accordance with SE-213, except that the propagation of sound in the tube or pipe wall shall be in the axial direction instead of the circumferential direction. Figure NB-2552-1 illustrates the characteristic oblique entry of

Page 36

sound into the pipe or tube wall and the axial direction of ultrasonic energy propagation to detect transverse notches or similar surface discontinuities.

**FIG. NB-2552-1 AXIAL PROPAGATION
OF SOUND IN TUBE WALL**

FIG. NB-2552-1 AXIAL PROPAGATION OF SOUND IN TUBE WALL

(3) *Acceptance Standards.* Products with defects that produce indications in excess of the indications produced by the standard defects in the reference specimen are unacceptable unless the defects are eliminated or repaired in accordance

with NB-2558 or NB-2559.

(b) Examination Procedure for Fittings

(1) Procedure. The procedure for ultrasonic examination of fittings shall be in accordance with the requirements of SA-388 for straight beam examination and, where feasible, angle-beam examination in two circumferential directions.

(2) Acceptance Standards. Fittings shall be unacceptable if straight beam examination shows one or more reflectors which produce indications accompanied by complete loss of back reflection not associated with or attributable to the geometric configuration, or if angle beam examination results show one or more reflectors which produce indications exceeding in amplitude the indications from the calibrated notch. Complete loss of back reflection is assumed when the back reflection falls below 5% of full calibration screen height.

(c) Reference Specimens

(1) The reference specimen shall be of the same nominal diameter and thickness, and of the same nominal composition and heat-treated condition as the product which is being examined. For circumferential scanning, the standard defects shall be axial notches or grooves on the outside and inside surfaces of the reference specimen, and shall have a length of approximately 1 in. (25 mm) or less, a width not to exceed $\frac{1}{16}$ in. (1.6 mm) for a square notch or U-notch, a width proportional to the depth for a V-notch, and a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the nominal wall thickness. For axial scanning in accordance with SE-213, a transverse (circumferential) notch shall be introduced on the inner and outer surfaces of the standard. Dimensions of the transverse notch shall not exceed those of the longitudinal notch. The reference specimen may be the product being examined.

(2) The reference specimen shall be long enough to simulate the handling of the product being examined through the examination equipment. When more than one standard defect is placed in a reference specimen, the defects shall be located so that indications from each defect are separate and distinct without mutual interference or amplification. All upset metal and burrs adjacent to the reference notches shall be removed.

(d) Checking and Calibration of Equipment. The proper functioning of the examination equipment shall be checked and the equipment shall be calibrated by the use of the reference specimens, as a minimum:

(1) at the beginning of each production run of a given size and thickness of a given material;

(2) after each 4 hr or less during the production run;

(3) at the end of the production run;

(4) at any time that malfunctioning is suspected. If, during any check, it is determined that the examination equipment is not functioning properly, all of the product that has been examined since the last valid equipment calibration shall be reexamined.

NB-2553 Radiographic Examination

(a) General. When radiographic examination is performed as an alternative for ultrasonic examination of the entire volume of the material, it shall apply to the entire volume of the pipe, tube, or fitting material. Acceptance standards specified for welds shall apply to the entire volume of material examined.

(b) Examination Procedure. The radiographic examination shall be performed in accordance with Article 2 of Section V, as modified by NB-5111.

(c) Acceptance Standard. Welds that are shown by radiography to have any of the following types of discontinuities are unacceptable:

(1) any type of crack or zone of incomplete fusion or penetration;

(2) any other elongated indication which has a length greater than:

(a) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive

(b) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive

(c) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm) where t is the thickness of the thinner portion of the weld;

(3) any group of aligned indications having an aggregate length greater than t in a length of $12t$, unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(4) rounded indications in excess of that shown as acceptable in Appendix VI.

NB-2554 Eddy Current Examination

(a) *General.* This examination method is restricted to materials with uniform magnetic properties and of sizes for which meaningful results can be obtained.

(b) *Examination Procedure.* The procedure for eddy current examination shall be in accordance with SE-426

Page 37

or SE-571. The procedure shall provide a sensitivity that will consistently detect defects by comparison with the standard defects included in the reference specimen in (d).

(c) *Acceptance Standards.* Products with defects that produce indications in excess of the reference standards are unacceptable.

(d) *Reference Specimens.* The reference specimen shall be of the same nominal diameter and thickness, and of the same nominal composition and heat-treated condition as the product that is being examined. The standard shall contain axial notches on the outside surface plus a $\frac{1}{16}$ in. (1.6 mm) diameter hole drilled through the wall. For copper-nickel alloy and nickel alloy materials, the standard shall have one notch extending axially on the outside surface and one notch extending axially on the inside surface plus a $\frac{1}{16}$ in. (1.6 mm) diameter hole drilled through the wall. These shall be used to establish the rejection level for the product to be tested. The reference notches shall have a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the wall thickness. The width of the notch shall not exceed $\frac{1}{16}$ in. (1.6 mm). The length shall be approximately 1 in. (25 mm) or less. The size of reference specimens shall be as specified in NB-2552(c).

(e) *Checking and Calibration of Equipment.* The checking and calibration of examination equipment shall be the same as in NB-2552(d).

NB-2555 Magnetic Particle Examination

Magnetic particle examination shall be performed in accordance with the requirements of NB-2545.

NB-2556 Liquid Penetrant Examination

Liquid penetrant examination shall be performed in accordance with the requirements of NB-2546.

NB-2557 Time of Examination

(a) Products that are quenched and tempered shall be examined, as required, after the quenching and tempering heat treatment.

(b) Products that are not quenched and tempered shall receive the required examinations as follows.

(1) Ultrasonic or eddy current examination, when required, shall be performed after final heat treatment, except postweld heat treatment.

(2) Radiographic examination, when required, may be performed prior to any required postweld heat treatment.

(3) Magnetic particle or liquid penetrant examination, including repair welds, shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment for P-No. 1 (Section IX of the Code) materials of 2 in. (51 mm) and less nominal thickness.

(4) Forgings and rolled bars which are to be bored and/or turned to form tubular parts or fittings shall be examined after boring and/or turning, except for threading. Fittings shall be examined after final forming.

NB-2558 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met.

(a) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(b) After defect elimination, the area is examined by the method which originally disclosed the defect to assure that the defect has been removed or reduced to an imperfection of acceptable size.

(c) If the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of NB-3000, the product shall be repaired in accordance with NB-2559.

NB-2559 Repair by Welding

Repair of defects shall be in accordance with NB-2539, except repair by welding is not permitted on copper-nickel alloy and nickel alloy heat exchanger tubes.

NB-2560 EXAMINATION AND REPAIR OF TUBULAR PRODUCTS AND FITTINGS WELDED WITH FILLER METAL

NB-2561 Required Examinations

(a) Welded tubular products (with filler metal) such as pipe made in accordance with SA-358, SA-409, SA-671, SA-672, and SA-691, and fittings made in accordance with the WPW grades of SA-234, SA-403, and SA-420, which are made by welding with filler metal, shall be treated as material; however, inspection by an Inspector and stamping with an NPT symbol shall be in accordance with Section III requirements. In addition to the NPT symbol, a numeral 1 shall be stamped below and outside the official Code Symbol.

Page 38

(b) In addition to the requirements of the material specification and of the Article, pipe and fittings shall comply with the following.

(1) The plate shall be examined in accordance with NB-2530 prior to forming, or alternatively, the finished product shall be examined by the ultrasonic method in accordance with NB-2562.

(2) All welds shall be examined 100% by radiography in accordance with the method and acceptance requirements of the base material specification, and by either the magnetic particle method in accordance with NB-2564 or the liquid penetrant method in accordance with NB-2565. If radiographic examination of welds is not specified in the basic material specification, the welds shall be examined by the radiographic method in accordance with NB-2563. The radiographic film and a radiographic report showing film locations shall be provided with the Certified Material Test Report.

NB-2562 Ultrasonic Examination

The ultrasonic examination shall be performed in accordance with the requirements of NB-2552.

NB-2563 Radiographic Examination

The radiographic examination shall be performed in accordance with the requirements of NB-2553.

NB-2565 Magnetic Particle Examination

The magnetic particle examination shall be performed in accordance with the requirements of NB-2545.

NB-2566 Liquid Penetrant Examination

The liquid penetrant examination shall be performed in accordance with the requirements of NB-2546.

NB-2567 Time of Examination

The time of examination shall be in accordance with the requirements of NB-2557, except that for magnetic particle or liquid penetrant examination of welds, including repair welds, for P-No. 1 (Section IX of the Code), examination may be performed prior to postweld heat treatment.

NB-2568 Elimination of Surface Defects

Unacceptable surface defects shall be removed in accordance with the requirements of NB-2558.

NB-2569 Repair by Welding

When permitted by the basic material specification, base material defects shall be repair welded in accordance with the requirements of NB-2559. Repair welding of weld seam defects shall be in accordance with NB-4450.

NB-2570 EXAMINATION AND REPAIR OF STATICALLY AND CENTRIFUGALLY CAST PRODUCTS

In addition to the requirements of the material specification and of this Article, statically and centrifugally cast products shall comply with the following subparagraphs.

NB-2571 Required Examination

Cast products shall be examined by the radiographic method, except cast ferritic steels which shall be examined by either the radiographic or ultrasonic method, or a combination of both methods, as required for the product form by Table NB-2571-1.

In addition, all cast products shall be examined on all external surfaces and all accessible internal surfaces by either the magnetic particle or liquid penetrant method. Machined surfaces, except threaded surfaces, of a cast product shall be examined by either the liquid penetrant or magnetic particle method after machining.

NB-2572 Time of Nondestructive Examination

NB-2572.1 Acceptance Examinations.

Acceptance examinations shall be performed at the time of manufacture as stipulated in the following and Table NB-2571-1.

(a) *Ultrasonic Examination.* Ultrasonic examination, if required, shall be performed at the same stage of manufacture as required for radiography.

(b) *Radiographic Examination.* Radiography may be performed prior to heat treatment and may be performed prior to or after finish machining at the following limiting thicknesses.

(1) For finished thicknesses under $2\frac{1}{2}$ in. (64 mm), castings shall be radiographed within 20% of the finished thickness when Type 2 radiographic film is used or within $\frac{1}{2}$ in. (13 mm) of the finished thickness when Type 1 radiographic film is used. The penetrameter and the acceptance reference radiographs shall be based on the finished thickness.

(2) For finished thickness from $2\frac{1}{2}$ in. (64 mm) up to 6 in. (152 mm), castings shall be radiographed

within 20% of the finished thickness. The penetrameter and the acceptance reference radiographs shall be based on the finished thickness. Pages 40-40

TABLE NB-2571-1 REQUIRED EXAMINATIONS

Nominal Pipe Size	Item	Applicable Special Requirements for Class 1 Castings
Inlet piping connections of 2 in. and less	Cast products other than pumps and valves	Cast products shall be examined by the radiographic method, except cast ferritic steels, which shall be examined by either the radiographic or ultrasonic method, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by the ultrasonic method shall be examined by the radiographic method. In addition, all cast products shall be examined on all external surfaces and all accessible internal surfaces by either the magnetic particle or the liquid penetrant method. Machined surfaces, except threaded surfaces, of a cast product shall be examined by either the liquid penetrant or the magnetic particle method after machining.
	Cast pumps and valves	None
	Repair welds in pumps and valves of P-No. 1 or P-No. 8 material	None
	Repair welds in cast products, excluding repair welds in pumps and valves of P-No. 1 or P-No. 8 material	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, repair welds in cavities the depth of which exceed the lesser of $\frac{3}{8}$ in. or 10% of the section thickness shall be radiographed in accordance with NB-2575.
Inlet piping connections over 2 in. up to and including 4 in.	Cast products — See <i>Cast pumps and valves</i> below for exceptions	Cast products shall be examined by the radiographic method, except cast ferritic steels, which shall be examined by either the radiographic or the ultrasonic method, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by the ultrasonic method shall be examined by the radiographic method. In addition, all cast products shall be examined on all external surfaces and all accessible internal surfaces by either the magnetic particle or the liquid penetrant method. Machined surfaces, except threaded surfaces, of a cast product shall be examined by either the liquid penetrant or the magnetic particle method after machining.
	Cast pumps and valves	Magnetic particle or liquid penetrant examination may be performed, in lieu of volumetric examination, except the welding ends of cast pumps and valves shall be radiographed for a minimum distance of t (when t is the design section thickness of the weld) from the final weld end.
	Repair welds	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, repair welds in cavities the depth of which exceed the lesser of $\frac{3}{8}$ in. or 10% of the section thickness shall be radiographed in accordance with NB-2575.

(continued)

TABLE NB-2571-1 REQUIRED EXAMINATIONS

TABLE NB-2571-1 REQUIRED EXAMINATIONS (CONT'D)

Nominal Pipe Size	Item	Applicable Special Requirements for Class 1 Castings
Inlet piping connections over 4 in.	Cast products	Cast products shall be examined by the radiographic method, except cast ferritic steels, which shall be examined by either the radiographic or the ultrasonic method, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by the ultrasonic method shall be examined by the radiographic method. In addition, all cast products shall be examined on all external surfaces and all accessible internal surfaces by either the magnetic particle or the liquid penetrant method. Machined surfaces, except threaded surfaces, of a cast product shall be examined by either the liquid penetrant or the magnetic particle method after machining.
	Repair welds	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, repair welds in cavities the depth of which exceed the lesser of $\frac{3}{8}$ in. or 10% of the section thickness shall be radiographed in accordance with NB-2575.

TABLE NB-2571-1 REQUIRED EXAMINATIONS (CONT'D)

(3) For finished thicknesses over 6 in. (152 mm), castings shall be radiographed with $\frac{1}{2}$ in. (13 mm) or 15% of the finished thickness, whichever is greater. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(c) Radiography of castings for pumps and valves may be performed in as-cast or rough machined thickness exceeding the limits of (b)(1), (b)(2), or (b)(3) above, subject to the following conditions.

(1) When the thickness of the as-cast or rough machined section exceeds 2 in. (51 mm), acceptance shall be based on reference radiographs for the next lesser thickness; e.g., if the section being radiographed exceeds $4\frac{1}{2}$ in. (114 mm), use reference radiographs of ASTM E 186-75 (reapproved 1979). The penetrometer shall be based on the thickness of the section being radiographed.

(2) When the thickness of the as-cast or rough machined section is 2 in. (51 mm) or less, the reference radiographs of ASTM E 446-78 shall be used and the penetrometer shall be based on the final section thickness.

(3) Weld ends for a minimum distance of t or $\frac{1}{2}$ in. (13 mm), whichever is less (where t is the design section thickness of the weld), from the final welding end shall be radiographed at a thickness within the limits given in (b)(1), (b)(2), or (b)(3) above as applicable. As an alternative, the weld ends may be radiographed in the as-cast or rough machined thickness in accordance with (c)(1) and (c)(2) above, and the penetrometer shall be based on the final section thickness.

(d) *Magnetic Particle or Liquid Penetrant Examination.* Magnetic particle or liquid penetrant examination shall be performed after the final heat treatment required by the material specification. Repair weld areas shall be examined after postweld heat treatment when a postweld heat treatment is performed, except that repair welds in P-No. 1 (see Section IX of the Code) material 2 in. (51 mm) nominal thickness and less may be examined prior to postweld heat treatment. For cast products with machined surfaces, all finished machined surfaces, except threaded surfaces and small deep holes, shall also be examined by the magnetic particle or the liquid penetrant method.

NB-2573 Provisions for Repair of Base Material by Welding

The Material Organization may repair, by welding, products from which defects have been removed, provided the requirements of this Article are met.

NB-2573.1 Defect Removal.

The defects shall be removed or reduced to an imperfection of acceptable size by suitable mechanical or thermal cutting or gouging methods, and the cavity prepared for repair. When thermal cutting is performed, consideration shall be given to preheating the material.

Page 41

NB-2573.2 Repair by Welding.

The Material Organization may repair castings by welding after removing the material containing unacceptable defects. The depth of the repair is not limited. A cored hole or access hole may be closed by the Material Organization by welding in accordance with the requirements of this paragraph, provided the hole is closed by filler metal only. If the hole is closed by welding in a metal insert, the welding shall be performed by a holder of a Certificate of Authorization in accordance with the requirements of the Code.

NB-2573.3 Qualification of Welding Procedures and Welders.

Each manufacturer is responsible for the welding done by his organization and shall establish the procedures and conduct the tests required by NB-4000 and by Section IX of the Code in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures. He is also responsible for the welding performed by his subcontractors and shall assure himself that the subcontractors conduct the tests required by NB-4000 and by Section IX of the Code in order to qualify their welding procedures and the performance of their welders and welding operators.

NB-2573.4 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NB-2573.5 Examination of Repair Welds

(a) Each repair weld shall be examined by the magnetic particle method in accordance with the requirements of NB-2577 or by the liquid penetrant method in accordance with the requirements of NB-2576. In addition, when radiography is specified in the order for the original casting, repair cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the nominal wall thickness, shall be radiographed after repair except that weld slag, including elongated slag, shall be considered as inclusions under Category B of the applicable reference radiographs. The total area of all inclusions, including slag inclusions, shall not exceed the limits of the applicable severity level of Category B of the reference radiographs. The penetrameter and the acceptance standards for radiographic examination of repair welds shall be based on the actual section thickness at the repair area.

(b) Examination of repair welds in P-No. 1 and P-No. 8 material is not required for pumps and valves with inlet piping connections NPS 2 (DN 50) and less.

NB-2573.6 Heat Treatment After Repairs.

The material shall be heat treated after repair in accordance with the heat treatment requirements of NB-4620, except that the heating and cooling rate limitations of NB-4623 do not apply.

NB-2573.7 Elimination of Surface Defects.

Surface defects shall be removed by grinding or machining provided the requirements of (a) through (c) below are met.

(a) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(b) After defect elimination, the area is reexamined by the magnetic particle method in accordance with NB-2577 or the liquid penetrant method in accordance with NB-2576 to assure that the defect has been removed or reduced to an imperfection of acceptable size.

(c) If the elimination of the defect reduces the section thickness below the minimum required by the specification or

drawing, the casting shall be repaired in accordance with NB-2539.

NB-2573.8 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the nominal wall thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart that shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film, when radiography is specified in the order for the original casting.

NB-2574 Ultrasonic Examination of Ferritic Steel Castings

Ultrasonic examination shall be performed in accordance with T-541.4 of Article 5 of Section V. Each manufacturer shall certify that the procedure is in accordance with the requirements of NB-2574 and shall make the procedure available for approval upon request.

NB-2574.1 Acceptance Standards

(a) The Quality Levels of SA-609 as shown in Section V shall apply for the casting thicknesses indicated:

- (1) Quality Level 1 for thicknesses up to 2 in. (51 mm);
- (2) Quality Level 3 for thicknesses 2 in. (51 mm) to 4 in. (102 mm);
- (3) Quality Level 4 for thicknesses greater than 4 in. (102 mm).

(b) In addition to the Quality Level requirements stated in (a) above, the requirements in (1) through (5) below shall apply for both straight beam and angle beam examination.

Page 42

(1) Areas giving indications exceeding the Amplitude Reference Line with any dimension longer than those specified in the following tabulation are unacceptable:

UT Quality Level	Longest Dimension of Area^{6, 7, 8}
1	1.5 in.
2	2.0 in.
3	2.5 in.
4	3.0 in.

(2) Quality Level 1 shall apply for the volume of castings within 1 in. (25 mm) of the surface regardless of the overall thickness.

(3) Discontinuities indicated to have a change in depth equal to or greater than one-half the wall thickness or 1 in. (25 mm) (whichever is less) are unacceptable.

(4) Two or more imperfections producing indications in the same plane with amplitudes exceeding the Amplitude Reference Line and separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable if they cannot be encompassed within an area less than that of the Quality Level specified in (b)(1) above.

(5) Two or more imperfections producing indications greater than permitted for Quality Level 1 for castings less than 2 in. (51 mm) in thickness, greater than permitted for Quality Level 2 for thicknesses 2 in. (51 mm) through 4 in. (102 mm), and greater than permitted for Level 3 for thicknesses greater than 4 in. (102 mm), separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable, if they cannot be encompassed in an area less than that of the Quality Level requirements stated in (a) above.

NB-2575 Radiographic Examination

6 The areas for the Ultrasonic Quality Levels in SA-609 refer to the surface area on the casting over which continuous indication, exceeding the transfer corrected distance amplitude curve, is maintained.

7 Areas are to be measured from dimensions of the movement of the search unit, using the center of the search unit as the reference point.

8 In certain castings, because of very long metal path distances or curvature of the examination surfaces, the surface area over which a given discontinuity is detected may be considerably larger or smaller than the actual area of the discontinuity in the casting; in such cases, other criteria which incorporate a consideration of beam angles or beam spread must be used for realistic evaluation of the discontinuity.

NB-2575.1 Examination.

Cast pressure-retaining materials shall be examined by the radiographic method when specified in the order for the original castings, except that cast ferritic steels may be examined by either the radiographic or ultrasonic method, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by ultrasonic methods shall be examined by the radiographic method.

NB-2575.2 Extent.

Radiographic examination shall be performed on pressure-retaining castings such as vessel heads and flanges, valve bodies, bonnets and disks, pump casings and covers, and piping and fittings. The extent of radiographic coverage shall be of the maximum feasible volume and, when the shape of the casting precludes complete coverage, the coverage shall be at least as exemplified in the typical sketches as shown in Fig. NB-2575.2-1.

NB-2575.3 Examination Procedure.

The radiographic examination shall be performed in accordance with Article 2 of Section V, with the following modifications.

(a) *Film Selection.* Only Types 1, 2, and 3 are permitted.

(b) *Radiographic Density.* The transmitted film density through the radiographic image of the body of the appropriate penetrameter and the area of interest shall be 1.3 minimum for single film viewing. For composite viewing of multiple film exposures, each film of the composite set shall have a minimum density of 1.0. The maximum density shall be 4.0 for either single or composite viewing. A tolerance of 0.05 in density is allowed for variations between densitometer readings.

(c) The requirements of T-274 and T-285 of Article 2 of Section V need not be met.

(d) *Image Quality Indicator (IQI) Design.* Penetrameters shall be manufactured and identified in accordance with the requirements or alternates allowed in SE-142 and Appendices.

(e) *Image Quality Indicator (IQI) Selection.* The radiographic quality level shall be 2-4 *T* for section thicknesses up to and including $\frac{3}{4}$ in. (19 mm) and 2-2 *T* for section thicknesses greater than $\frac{3}{4}$ in. (19 mm). Radiographic quality is defined in Note 2 of SE-94.

(f) When radiographing weld ends of cast valves, NPS 4 and less, double-wall radiography may be used subject to the conditions of (1) and (2) below.

(1) The penetrameter thickness shall be based on the design section thickness of the double wall, excluding the weld preparation lip.

(2) Acceptance standards shall be based on nominal single-wall thickness.

Page 45

Pages 44-44

(a) Typical Volute-Type Pump Case

GENERAL NOTES:

- (a) Radiographic examination areas shall be indicated by a circle at each change of direction. The examination symbol for radiography shall be indicated as RT.
- (b) For nondestructive examination areas of revolution, the area shall be indicated by the examine-all-around symbol: — RT — ⌀
- (c) The sketches are typical and are to be used as a guide for minimum required coverage. Even though a sketch may be titled, "pump" or "valve," the coverage shown by the configurations may be applied interchangeably.

FIG. NB-2575.2-1 TYPICAL PRESSURE-RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

NB-2575.4 Procedure Requirements.

Radiographic examination shall be performed in accordance with a written procedure. Each manufacturer shall certify that the procedure is in accordance with the requirements of NB-2575. The procedure shall be available for the interpretation of the films and shall be submitted together with the radiographs. Each procedure shall include at least the following information:

- (a) the type of material to be radiographed;
- (b) the material thickness ranges to be radiographed;
- (c) the type of radiation source, actual or maximum source size or focal spot, X-ray equipment voltage rating and manufacturer. The equipment manufacturer's or supplier's publications, such as technical manuals, decay curves, or written statements documenting the actual or maximum source size or focal spot, shall be acceptable as source size verification. For X-ray machines 320 kV and less, the focal spot size may be determined by the pinhole method;⁹
- (d) type and thickness of intensifying screens and filters;
- (e) minimum source-to-film distance.

NB-2575.5 Radiographic Setup Information.

To aid in proper interpretation of radiographs, details of the radiographic examination setup used shall accompany each group of radiographs. As a minimum, the information shall include:

- (a) film brand and the type and number of films in the cassette;
- (b) for multiple film technique, state whether viewing is to be single or superimposed;
- (c) blocking or masking technique, if used;
- (d) isotope or X-ray voltage used;
- (e) source-to-film distance used;
- (f) distance between film and object when film/cassette is not in contact with object;
- (g) geometric arrangement for the radiograph(s) (sketch);
- (h) orientation of location markers;
- (i) description of how internal markers, when used, locate area of interest;

⁹ Nondestructive Testing Handbook, Volume I, First Edition, pp. 14.32, 14.33, "Measuring Focal-Spot Size." Also, pp. 20, 21 of Radiography in Modern Industry, Fourth Edition.

(j) location markers, such as lead numbers or letters, which shall appear as radiographic images on the film, shall be permanently stamped on the surface of the casting being radiographed in a manner permitting the area of interest on a radiograph to be accurately located on the casting and providing evidence on the radiograph that the extent of coverage required by NB-2575.2 has been obtained. On castings or sections of castings where stamping is not feasible, the radiographic procedure shall so state, in which case a radiographic film location map shall be provided.

NB-2575.6 Acceptance Criteria.

Castings shall meet the acceptance requirements of Severity Level 2 of ASTM E 446-72, E 446-75, or E 446-78, Reference Radiographs for Steel Castings up to 2 In. in Thickness, ASTM E 186-67, E 186-73, or E 186-75, Reference Radiographs for Heavy-Walled (2 to 4 $\frac{1}{2}$ in.) Steel Castings, or ASTM E 280-68, E 280-72, or E 280-75, Reference Radiographs for Heavy-Walled (4 $\frac{1}{2}$ to 12 in.) Steel Castings, as applicable for the thickness being radiographed except that Category D, E, F, or G defects are not acceptable. The requirements of ASTM E 280-68, E 280-72, or E 280-75 shall apply for castings over 12 in. in thickness.

NB-2576 Liquid Penetrant Examination

(a) Castings shall be examined, if required, on all accessible surfaces by the liquid penetrant method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by bleeding out of the penetrant; however, localized surface discontinuities as may occur from machining marks, scale, or dents, may produce indications which are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation that would mask indications of defects are unacceptable. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. (1.6 mm). Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

Page 46

(4) ten or more indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NB-2577 Magnetic Particle Examination (for Ferritic Steel Products Only)

(a) Castings of magnetic material shall be examined, if required, on all accessible surfaces by a magnetic particle method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by retention of the examination medium. All indications are not necessarily defects since certain metallurgical discontinuities and magnetic permeability variations may produce indications that are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Nonrelevant indications which would mask indications of defects are unacceptable. Surface conditioning may precede the reexamination. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NB-2580 EXAMINATION OF BOLTS, STUDS, AND NUTS

NB-2581 Required Examination

All bolting material shall be visually examined in accordance with NB-2582. Nominal sizes greater than 1 in. (25 mm) shall be examined by either the magnetic particle or the liquid penetrant method. In addition, nominal sizes greater than 2 in. (51 mm) but not over 4 in. (102 mm) shall be examined by the ultrasonic method as required by NB-2585 and nominal sizes greater than 4 in. (102 mm) shall be examined by the ultrasonic method as required by NB-2586.

NB-2582 Visual Examination

The areas of threads, shanks, and heads of final machined parts shall be visually examined. Harmful discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

NB-2583 Magnetic Particle Examination (for Ferritic Steel Bolting Material Only)

NB-2583.1 Examination Procedure.

All bolts, studs, and nuts greater than 1 in. (25 mm) nominal bolt size shall be examined by the magnetic particle method in accordance with ASTM A 275-78. If desired, the supplier may perform liquid penetrant examination in accordance with NB-2584 instead of magnetic particle examination. Such examination shall be performed on the finished component after threading or on the materials stock at approximately the finished diameter before threading and after heading (if involved). This examination shall be performed on all accessible surfaces.

NB-2583.2 Evaluation of Indications

(a) All indications shall be evaluated in terms of the acceptance standards. Linear indications are those indications in which the length is more than three times the width. Rounded indications are those which are circular or elliptical with the length equal to or less than three times the width.

(b) All indications are not necessarily relevant: leakage of magnetic fields and permeability variations may produce indications that are not relevant to the detection of unacceptable discontinuities. Indications with major dimensions of $\frac{1}{16}$ in. (1.6 mm) or less are not relevant.

(c) Any indication that is believed to be nonrelevant, and that is larger than acceptable, shall be considered to be a defect and shall be reexamined after light surface conditioning.

Page 47

(d) Any indication observed during such reexamination shall be considered relevant and shall be evaluated in terms of the acceptance standards.

(e) As an alternative to magnetic particle reexamination, other nondestructive examination means (such as liquid penetrant examination for surface discontinuities) may be used to determine relevancy.

NB-2583.3 Acceptance Standard.

Linear nonaxial indications are unacceptable. Linear axial indications greater than 1 in. (25 mm) in length are unacceptable.

NB-2584 Liquid Penetrant Examination

NB-2584.1 Examination Procedure.

All bolts, studs, and nuts greater than 1 in. (25 mm) nominal bolt size shall be examined by a liquid penetrant method in accordance with the methods of Article 6, Section V. Such examination shall be performed on the finished component after threading or on the materials stock at approximately the finished diameter before threading and after heading (if involved).

NB-2584.2 Evaluation of Indications.

All indications shall be evaluated in terms of the acceptance standards. Linear indications are those indications in which the length is more than three times the width. Rounded indications are those which are circular to elliptical with the length equal to or less than three times the width. All penetrant indications are not necessarily relevant. Surface imperfections such as machining marks and scratches may produce indications that are nonrelevant to the detection of unacceptable discontinuities. Broad areas of pigmentation, which could mask indications of defects, are unacceptable. Indications with major dimensions of $\frac{1}{16}$ in. (1.6 mm) or less are not relevant. Any indication that is believed to be nonrelevant, and that is larger than acceptable, shall be considered to be a defect and shall be reexamined after light surface conditioning. Any area of pigmentation also shall be reexamined after recleaning or light surface conditioning, as appropriate. Any indication observed during such reexamination shall be considered relevant and shall be evaluated in terms of the acceptance standards.

NB-2584.3 Acceptance Standard.

Linear nonaxial indications are unacceptable. Linear axial indications greater than 1 in. (25 mm) long are unacceptable.

NB-2585 Ultrasonic Examination for Sizes Greater Than 2 in. (51 mm)

All bolts, studs, and nuts greater than 2 in. nominal bolt size shall be ultrasonically examined over the entire surface prior to threading in accordance with the following requirements.

NB-2585.1 Ultrasonic Method.

Examination shall be carried out by the straight beam, radial-scan method in accordance with SA-388 of Article 23 of Section V.

NB-2585.2 Examination Procedure.

Examination shall be performed at a nominal frequency of 2.25 MHz with a search unit not to exceed 1 sq in. (645 mm²).

NB-2585.3 Calibration of Equipment.

Calibration sensitivity shall be established by adjustment of the instrument so that the first back reflection is 75% to 90% of full-screen height.

NB-2585.4 Acceptance Standard.

Any discontinuity that causes an indication in excess of 20% of the height of the first back reflection or any discontinuity that prevents the production of a first back reflection of 50% of the calibration amplitude is not acceptable.

NB-2586 Ultrasonic Examination for Sizes Over 4 in. (102 mm)

In addition to the requirements of NB-2585, all bolts, studs, and nuts over 4 in. (102 mm) nominal bolt size shall be ultrasonically examined over the entire end surface before or after threading in accordance with the following requirements.

NB-2586.1 Ultrasonic Method.

Examination shall be carried out by the straight beam, longitudinal-scan method.

NB-2586.2 Examination Procedure.

Examination shall be performed at a nominal frequency of 2.25 MHz with a search unit having a circular cross section with a diameter not less than $\frac{1}{2}$ in. (13 mm) nor more than $1\frac{1}{8}$ in. (29 mm).

NB-2586.3 Calibration of Equipment.

Calibration shall be established on a test bar of the same nominal composition and diameter as the production part and a minimum of one-half of the length. A $\frac{3}{8}$ in. (10 mm) diameter by 3 in. (76 mm) deep flat-bottom hole shall be drilled in one end of the bar and plugged to full depth. A distance-amplitude curve shall be established by scanning from both ends of the test bar.

NB-2586.4 Acceptance Standard.

Any discontinuity that causes an indication in excess of that produced

Page 48

by the calibration hole in the reference specimen as corrected by the distance-amplitude curve is not acceptable.

NB-2587 Time of Examination

Acceptance examinations shall be performed after the final heat treatment required by the basic material specification.

NB-2588 Elimination of Surface Defects

Unacceptable surface defects on finished bolts, studs, and nuts are not permitted, and are cause for rejection.

NB-2589 Repair by Welding

Weld repairs of bolts, studs, and nuts are not permitted.

NB-2600 MATERIAL ORGANIZATIONS' QUALITY SYSTEM PROGRAMS

NB-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 and NCA-3856 shall be met as required by NB-2130 and NB-2150, respectively. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, for brazing material, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Assurance Program (NCA-4000) shall include measures to provide assurance that the material is furnished in accordance with the material specification and with the applicable requirements of this Subsection.

(c) For the purpose of this paragraph, small products are defined as given in (1) through (5) below:

- (1) pipe, tube (except heat exchanger tube), pipe fittings, and flanges 2 in. nominal pipe size (DN 50) and less;
- (2) bolting material, including studs, nuts, and bolts of 1 in. (25 mm) nominal diameter and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;
- (4) material for pumps and valves with inlet pipe connections of 2 in. nominal pipe size (DN 50) and less;
- (5) material exempted by NB-2121(c).

NB-2700 DIMENSIONAL STANDARDS

Dimensions of standard items shall comply with the standards and specifications listed in Table NB-3132-1.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NB-3000

NB-3100 GENERAL DESIGN

NB-3110 LOADING CRITERIA

NB-3111 Loading Conditions

The loadings that shall be taken into account in designing a component include, but are not limited to, those in (a) through (g) below:

- (a) internal and external pressure;
- (b) impact loads, including rapidly fluctuating pressures;
- (c) weight of the component and normal contents under operating or test conditions, including additional pressure due to static and dynamic head of liquids;
- (d) superimposed loads such as other components, operating equipment, insulation, corrosion resistant or erosion resistant linings, and piping;
- (e) wind loads, snow loads, vibrations, and earthquake loads where specified;
- (f) reactions of supporting lugs, rings, saddles, or other types of supports;
- (g) temperature effects.

NB-3112 Design Loadings

The Design Loadings shall be established in accordance with NCA-2142.1 and the following subparagraphs.

NB-3112.1 Design Pressure

(a) The specified internal and external Design Pressures to be used in this Subsection shall be established in accordance with NCA-2142.1(a). They shall be used in the computations made to show compliance with the stress intensity limits of NB-3221, NB-3227.1, NB-3227.2, NB-3227.4, NB-3228.1, NB-3228.2, and NB-3231. The specified service pressure at the appropriate time shall be used in the computations made to show compliance with the stress intensity limits of NB-3222, NB-3228.3, and NB-3232. When the occurrence of different pressures during operation can be predicted for different zones of a component, the Design Pressure of the different zones may be based on their predicted pressures.

(b) All pressures referred to in this Article are to be taken as pounds per square inch, psi, above atmospheric pressure, unless otherwise stated.

NB-3112.2 Design Temperature

(a) The specified Design Temperature shall be established in accordance with NCA-2142.1(b). It shall be used in computations involving the Design Pressure and coincidental Design Mechanical Loads. The actual metal temperature at the point under consideration shall be used in all computations where the use of the specified service pressure is required.

(b) All temperatures referred to in this Subsection are the metal temperatures expressed in degrees Fahrenheit (°F) unless otherwise stated.

(c) Where a component is heated by tracing, induction coils, jacketing, or internal heat generation, the effect of such heating shall be incorporated in the establishment of the Design Temperature.

NB-3112.3 Design Mechanical Loads.

The specified Design Mechanical Loads shall be established in accordance with NCA-2142.1(c). They shall be used in conjunction with the Design Pressure.

NB-3112.4 Design Stress Intensity Values.

Design stress intensity values for materials are listed in Section II, Part D, Subpart 1, Tables 2A, 2B, and 4. The material shall not be used at metal and design temperatures above those for which stress intensity values are listed. The values in the Table may be interpolated for intermediate temperatures.

NB-3113 Service Conditions

Each service condition to which the components may be subjected shall be classified in accordance with NCA-2142 and Service Limits [NCA-2142.4(b)] designated in the Design Specifications in such detail as will provide a complete basis for design, construction, and inspection

Page 62

in accordance with this Article. The requirements of (a) and (b) below shall also apply.

(a) *Level B Conditions.* The estimated duration of service conditions for which Level B Limits are specified shall be included in the Design Specifications.

(b) *Level C Conditions.* The total number of postulated occurrences for all specified service conditions for which Level C Limits are specified shall not cause more than 25 stress cycles having an S_a value greater than that for 10^6 cycles from the applicable fatigue design curves of Figs. I-9.0.

NB-3120 SPECIAL CONSIDERATIONS

NB-3121 Corrosion

Material subject to thinning by corrosion, erosion, mechanical abrasion, or other environmental effects shall have provision made for these effects during the design or specified life of the component by a suitable increase in or addition to the thickness of the base metal over that determined by the design formulas. Material added or included for these purposes need not be of the same thickness for all areas of the component if different rates of attack are expected for the various areas. It should be noted that the tests on which the design fatigue curves (Figs. I-9.0) are based did not include tests in the presence of corrosive environments which might accelerate fatigue failure.

NB-3122 Cladding

The rules of the following subparagraphs apply to the analysis of clad components constructed of material permitted in Section II, Part D, Subpart 1, Tables 2A and 2B.

NB-3122.1 Primary Stresses.

No structural strength shall be attributed to the cladding in satisfying NB-3221.

NB-3122.2 Design Dimensions.

The dimensions given in (a) and (b) below shall be used in the design of the component:

(a) for components subjected to internal pressure, the inside diameter shall be taken at the nominal inner face of the cladding;

(b) for components subjected to external pressure, the outside diameter shall be taken at the outer face of the base metal.

NB-3122.3 Secondary and Peak Stresses.

In satisfying NB-3222.2 and NB-3222.4, the presence of the cladding shall be considered with respect to both the thermal analysis and the stress analysis. The stresses in both materials shall be limited to the values specified in

NB-3222.2 and NB-3222.4. However, when the cladding is of the integrally bonded type and the nominal thickness of the cladding is 10% or less of the total thickness of the component, the presence of the cladding may be neglected.

NB-3122.4 Bearing Stresses.

In satisfying NB-3227.1, the presence of cladding shall be included.

NB-3123 Welding

NB-3123.1 Dissimilar Welds.

In satisfying the requirements of this Subarticle, caution should be exercised in design and construction involving dissimilar metals having different coefficients of thermal expansion in order to avoid difficulties in service.

NB-3123.2 Fillet Welded Attachments.

Fillet welds conforming to Fig. NB-4427-1 may be used for attachments to components except as limited by NB-4433. Evaluation for cyclic loading shall be made in accordance with the appropriate Subarticle of NB-3000, and shall include consideration of temperature differences between the component and the attachment, and of expansion or contraction of the component produced by internal or external pressure.

NB-3124 Environmental Effects

Changes in material properties may occur due to environmental effects. In particular, fast neutron irradiation (>1 MeV) above a certain level may result in significant increase in the brittle fracture transition temperature and deterioration in the resistance to fracture at temperatures above the transition range (upper shelf energy). Therefore, nozzles or other structural discontinuities in ferritic vessels should preferably not be placed in regions of high neutron flux.

NB-3125 Configuration

Accessibility to permit the examinations required by the Edition and Addenda of Section XI as specified in the Design Specification for the component shall be provided in the design of the component.

NB-3130 GENERAL DESIGN RULES

NB-3131 Scope

Design rules generally applicable to all components are provided in the following paragraphs. The design Subarticle for the specific component provides rules

Page 63

applicable to that particular component. In case of conflict between NB-3130 and the design rules for a particular component, the component design rules govern.

NB-3132 Dimensional Standards for Standard Products

Dimensions of standard products shall comply with the standards and specifications listed in Table NB-3132-1 when the standard or specification is referenced in the specific design Subarticle. However, compliance with these standards does not replace or eliminate the requirements for stress analysis when called for by the design Subarticle for a specific component.

NB-3133 Components Under External Pressure

NB-3133.1 General.

Rules are given in this paragraph for determining the stresses under external pressure loading in spherical and cylindrical shells with or without stiffening rings, and tubular products consisting of pipes, tubes, and fittings. Charts for determining the stresses in shells, hemispherical heads, and tubular products are given in Section II, Part D, Subpart 3.

NB-3133.2 Nomenclature.

The symbols used in this paragraph are defined as follows:

A	= factor determined from Fig. G in Section II, Part D, Subpart 3 and used to enter the applicable material chart in Section II, Part D, Subpart 3. For the case of cylinders having D_o/T values less than 10, see NB-3133.3(b). Also, factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a stiffening ring, corresponding to the factor B and the design metal temperature for the shell under consideration.
A_s	= cross-sectional area of a stiffening ring, sq in.
B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a shell or stiffening ring at the design metal temperature, psi
D_o	= outside diameter of the cylindrical shell course or tube under consideration, in.
E	= modulus of elasticity of material at Design Temperature, psi. For external pressure and axial compression design in accordance with this Section, the modulus of elasticity to be used shall be taken from the applicable materials chart in Section II, Part D, Subpart 3. (Interpolation may be made between lines for intermediate temperatures.) The modulus of elasticity values shown in Section II, Part D, Subpart 3 for material groups may differ from those values listed in Section II, Part D, Subpart 2, Tables TM for specific materials. Section II, Part D, Subpart 3 values shall be applied only to external pressure and axial compression design.
I	= available moment of inertia of the combined ring-shell section about its neutral axis, parallel to the axis of the shell, in. ⁴ The width of the shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10\sqrt{D_o T}$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing area to more than one stiffening ring.
I_s	= required moment of inertia of the combined ring-shell section about its neutral axis parallel to the axis of the shell, in. ⁴
L	= total length, in., of a tube between tubesheets, or the design length of a vessel section, taken as the largest of the following: (1) the distance between head tangent lines plus one-third of the depth of each head if there are no stiffening rings; (2) the greatest center-to-center distance between any two adjacent stiffening rings; or (3) the distance from the center of the first stiffening ring to the head tangent line plus one-third of the depth of the head,

all measured parallel to the axis of the vessel, in.

L_s

= one-half the distance, in., from the center line of the stiffening ring to the next line of support on one side, plus one-half of the center line distance to the next line of support on the other side of the stiffening ring, both measured parallel to the axis of the component. A line of support is:

(1) a stiffening ring that meets the requirements of this paragraph;

(2) a circumferential line on a head at one-third the depth of the head from the head tangent line; or

(3) circumferential connection to a jacket for a jacketed section of a cylindrical shell.

P

= external design pressure, psi (gage or absolute, as required)

P_a

= allowable external pressure, psi (gage or absolute, as required)

R

= inside radius of spherical shell, in.

S

= the lesser of 1.5 times the stress intensity at design metal temperature from Section II, Part D, Subpart 1, Tables 2A and 2B, or 0.9 times the tabulated yield strength at design metal temperature from Section II, Part D, Subpart 1, Table Y-1, psi

Page 64

Page 65

T

= minimum required thickness of cylindrical shell or tube, or spherical shell, in.

T_n

= nominal thickness used, less corrosion allowance, of cylindrical shell or tube, in.

(3) Analysis per MSS-SP-87 is acceptable only for caps and reducers.	

TABLE NB-3132-1 DIMENSIONAL STANDARDS

NB-3133.3 Cylindrical Shells and Tubular Products

(a) The minimum thickness of cylindrical shells or tubular products under external pressure having D_o/T values equal to or greater than 10 shall be determined by the procedure given in Steps 1 through 8 below.

Step 1: Assume a value for T . Determine the ratios L/D_o and D_o/T .

Step 2: Enter Fig. G in Section II, Part D, Subpart 3 at the value of L/D_o determined in Step 1. For values of L/D_o greater than 50, enter the chart at a value of L/D_o of 50. For values of L/D_o less than 0.05, enter the chart at a value of L/D_o of 0.05.

Step 3: Move horizontally to the line for the value of D_o/T determined in Step 1. Interpolation may be made for intermediate values of D_o/T . From this intersection move vertically downward and read the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material/temperature under consideration. Move vertically to an intersection with the material/temperature line for the design temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material line, see Step 7.

Step 5: From the intersection obtained in Step 4 move horizontally to the right and read the value of B .

Step 6: Using this value of B , calculate the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{4B}{3D_o/T}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated using the following formula:

$$P_a = \frac{2AE}{3D_o/T}$$

Step 8: Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

(b) The minimum thickness of cylindrical shells or tubular products under external pressure having D_o/T values less than 10 shall be determined by the procedure given in Steps 1 through 4 below.

Step 1: Using the same procedure as given in (a) above, obtain the value of B . For values of D_o/T less than 4, the value of factor A can be calculated using the following formula:

$$A = \frac{1.1}{(D_o/T)^2}$$

For values of A greater than 0.10 use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{al} using the following formula:

$$P_{a1} = \left(\frac{2.167}{D_o/T} - 0.0833 \right) B$$

Step 3: Calculate a value P_{a2} using the following formula:

$$P_{a2} = \frac{2S}{D_o/T} \left(1 - \frac{1}{D_o/T} \right)$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2 or P_{a2} calculated in Step 3 shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NB-3133.4 Spherical Shells.

The minimum required thickness of a spherical shell under external pressure, either seamless or of built-up construction with butt joints, shall be determined by the procedure given in Steps 1 through 6 below.

Page 66

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{R/T}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the design temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values at A falling to the left of the material/temperature line, see Step 5.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B .

Step 4: Using the value of B obtained in Step 3, calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{B}{R/T}$$

Step 5: For values of A falling to the left of the applicable material/temperature line for the Design Temperature, the value of P_a can be calculated using the following formula:

$$P_a = \frac{0.0625E}{(R/T)^2}$$

Step 6: Compare P_a obtained in Step 4 or 5 with P . If P_a is smaller than P , select a larger value for T , and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NB-3133.5 Stiffening Rings for Cylindrical Shells

(a) The required moment of inertia of the combined ring-shell section is given by the formula:

$$I_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{10.9}$$

The available moment of inertia I for a stiffening ring shall be determined by the procedure given in Steps 1 through 6 below.

Step 1: Assuming that the shell has been designed and D_o , L_s , and T_n are known, select a member to be used for the stiffening ring and determine its area A and the value of I defined in NB-3133.2. Then calculate B by the formula:

$$B = \frac{3}{4} \left(\frac{PD_o}{T_n + A_s / L_s} \right)$$

Step 2: Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined in Step 1. If different materials are used for the shell and stiffening ring, then use the material chart resulting in the larger value for factor A in Steps 4 or 5 below.

Step 3: Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4: Move vertically to the bottom of the chart and read the value of A .

Step 5: For values of B falling below the left end of the material/temperature line for the design temperature, the value of A can be calculated using the following formula:

$$A = 2B/E$$

Step 6: If the required I_s is greater than the computed moment of inertia I for the combined-ring shell section selected in Step 1, a new section with a larger moment of inertia must be selected and a new I_s determined. If the required I_s is smaller than the computed I for the section selected in Step 1, that section should be satisfactory.

(b) Stiffening rings may be attached to either the outside or the inside of the component by continuous welding.

NB-3133.6 Cylinders Under Axial Compression.

The maximum allowable compressive stress to be used in the design of cylindrical shells and tubular products subjected to loadings that produce longitudinal compressive stresses in the shell or wall shall be the lesser of the values given in (a) or (b) below:

Page 67

(a) the S_m value for the applicable material at design temperature given in Section II, Part D, Subpart 1, Tables 2A and 2B;

(b) the value of the factor B determined from the applicable chart contained in Section II, Part D, Subpart 3, using the following definitions for the symbols on the charts:

R	= inside radius of the cylindrical shell or tubular product, in.
T	= minimum required thickness of the shell or tubular product, exclusive of the corrosion allowance, in.

The value of B shall be determined from the applicable chart contained in Section II, Part D, Subpart 3 as given in Steps 1 through 5 below.

Step 1: Using the selected values of T and R , calculate the value of factor A using the following formula:

$$A = \frac{0.125}{R/T}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the design temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 4.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B . This is the maximum allowable compressive stress for the values of T and R used in Step 1.

Step 4: For values of A falling to the left of the applicable material/temperature line, the value of B shall be calculated using the following formula:

$$B = \frac{AE}{2}$$

Step 5: Compare the value of B determined in Step 3 or 4 with the computed longitudinal compressive stress in the cylindrical shell or tube, using the selected values of T and R . If the value of B is smaller than the computed compressive stress, a greater value of T must be selected and the design procedure repeated until a value of B is obtained which is greater than the compressive stress computed for the loading on the cylindrical shell or tube.

NB-3134 Leak Tightness

Where a system leak tightness greater than that required or demonstrated by a hydrostatic test is required, the leak

tightness requirements for each component shall be set forth in the Design Specifications.

NB-3135 Attachments

(a) Except as permitted in (d), (e), or (f) below, attachments and connecting welds within the jurisdictional boundary of the component as defined in NB-1130 shall meet the stress limits of the component or NB-3200.

(b) The design of the component shall include consideration of the localized interaction effects and loads transmitted through the attachment to and from the pressure-retaining portion of the component. Localized interaction effects include thermal stresses, stress concentrations, and restraint of the pressure-retaining portion of the component.

(c) The first welded structural attachment within $2t$ of the pressure-retaining portion of the component, where t is the nominal thickness of the pressure-retaining material, shall be evaluated for cyclic loading. Evaluation shall be in accordance with the appropriate Subarticle of NB-3000 and shall be made at the juncture of the attachment to the component.

(d) Beyond $2t$ the appropriate design rules of NF-3000 may be used as a substitute for the design rules of NB-3000 for cast and forged portions of attachments which are in the component support load path.

(e) Nonstructural attachments shall meet the requirements of NB-4435.

(f) Beyond $2t$ the appropriate design rules of NG-3000 may be used as a substitute for the design rules of NB-3000 for portions of cast or forged attachments which are core support structures.

NB-3137 Reinforcement for Openings

The requirements applicable to vessels and piping are contained in NB-3330 and NB-3643, respectively.

Page 68

NB-3200 DESIGN BY ANALYSIS

NB-3210 DESIGN CRITERIA

NB-3211 Requirements for Acceptability

The requirements for the acceptability of a design by analysis are given in (a) through (d) below.

(a) The design shall be such that stress intensities will not exceed the limits described in this Subarticle and in NB-3100 and tabulated in Section II, Part D, Subpart 1, Tables 2A, 2B, and 4.

(b) The design details shall conform to the rules given in NB-3100 and those given in the Subarticle applicable to the specific component.

(c) For configurations where compressive stresses occur, in addition to the requirements in (a) and (b) above, the critical buckling stress shall be taken into account. For the special case of external pressure, NB-3133 applies.

(d) Protection against nonductile fracture shall be provided by satisfying one of the following provisions:

(1) performing an evaluation of service and test conditions by methods similar to those contained in Appendix G; or

(2) for piping, pump, and valve material thickness greater than $2\frac{1}{2}$ in. (64 mm) establishing a lowest service temperature¹ that is not lower than RT_{NDT} (NB-2331) + 100°F;

(3) for piping, pump, and valve material thickness equal to or less than $2\frac{1}{2}$ in. (64 mm), the requirements of NB-2332(a) shall be met at or below the lowest service temperature as established in the design specification.

NB-3212 Basis for Determining Stresses

The theory of failure, used in the rules of this Subsection for combining stresses, is the maximum shear stress theory. The maximum shear stress at a point is equal to one-half the difference between the algebraically largest and the algebraically

smallest of the three principal stresses at the point.

NB-3213 Terms Relating to Stress Analysis

Terms used in this Subsection relating to stress analysis are defined in the following subparagraphs.

1 Lowest service temperature is the minimum temperature of the fluid retained by the component or, alternatively, the calculated volumetric average metal temperature expected during normal operation, whenever pressure within the component exceeds 20% of the pre-operational system hydrostatic test pressure.

NB-3213.1 Stress Intensity.²

Stress intensity is the equivalent intensity of combined stress, or, in short, the stress intensity is defined as twice the maximum shear stress. In other words, the stress intensity is the difference between the algebraically largest principal stress and the algebraically smallest principal stress at a given point. Tensile stresses are considered positive and compressive stresses are considered negative.

NB-3213.2 Gross Structural Discontinuity.

Gross structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through the entire wall thickness of the pressure retaining member. Gross discontinuity type stresses are those portions of the actual stress distributions that produce net bending and membrane force resultants when integrated through the wall thickness. Examples of gross structural discontinuities are head-to-shell and flange-to-shell junctions, nozzles (NB-3331), and junctions between shells of different diameters or thicknesses.

NB-3213.3 Local Structural Discontinuity.

Local structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through a fractional part of the wall thickness. The stress distribution associated with a local discontinuity causes only very localized types of deformation or strain and has no significant effect on the shell type discontinuity deformations. Examples are small fillet radii, small attachments, and partial penetration welds.

NB-3213.4 Normal Stress.

Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in turn of two components, one of which is uniformly distributed and equal to the average value of stress across the thickness under consideration, and the other of which varies from this average value with the location across the thickness.

NB-3213.5 Shear Stress.

Shear stress is the component of stress tangent to the plane of reference.

NB-3213.6 Membrane Stress.

Membrane stress is the component of normal stress which is uniformly distributed and equal to the average value of stress across the thickness of the section under consideration.

2 This definition of stress intensity is not related to the definition of stress intensity applied in the field of Fracture Mechanics.

NB-3213.7 Bending Stress.

Bending stress is the variable component of normal stress described in NB-3213.4.

The variation may or may not be linear across the thickness.

NB-3213.8 Primary Stress.

Primary stress is any normal stress or a shear stress developed by an imposed loading which is necessary to satisfy the

Primary stress is any normal stress or a shear stress developed by an imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses which considerably exceed the yield strength will result in failure or, at least, in gross distortion. A thermal stress is not classified as a primary stress. Primary membrane stress is divided into general and local categories. A general primary membrane stress is one which is so distributed in the structure that no redistribution of load occurs as a result of yielding. Examples of primary stresses are:

- (a) general membrane stress in a circular cylindrical or a spherical shell due to internal pressure or to distributed live loads;
- (b) bending stress in the central portion of a flat head due to pressure.

NB-3213.9 Secondary Stress.

Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent material or by self-constraint of the structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur and failure from one application of the stress is not to be expected. Examples of secondary stresses are:

- (a) general thermal stress [NB-3213.13(a)];
- (b) bending stress at a gross structural discontinuity.

NB-3213.10 Local Primary Membrane Stress.

Cases arise in which a membrane stress produced by pressure or other mechanical loading and associated with a discontinuity would, if not limited, produce excessive distortion in the transfer of load to other portions of the structure. Conservatism requires that such a stress be classified as a local primary membrane stress even though it has some characteristics of a secondary stress. A stressed region may be considered local if the distance over which the membrane stress intensity exceeds $1.1S_m$ does not extend in the meridional direction more than $1.0\sqrt{Rt}$, where R is the minimum midsurface radius of curvature and t is the minimum thickness in the region considered. Regions of local primary stress intensity involving axisymmetric membrane stress distributions which exceed $1.1S_m$ shall not be closer in the meridional direction than $2.5\sqrt{Rt}$, where R is defined as $(R_1 + R_2)/2$ and t is defined as $(t_1 + t_2)/2$ (where t_1 and t_2 are the minimum thicknesses at each of the regions considered, and R_1 and R_2 are the minimum midsurface radii of curvature at these regions where the membrane stress intensity exceeds $1.1S_m$). Discrete regions of local primary membrane stress intensity, such as those resulting from concentrated loads acting on brackets, where the membrane stress intensity exceeds $1.1S_m$, shall be spaced so that there is no overlapping of the areas in which the membrane stress intensity exceeds $1.1S_m$.

NB-3213.11 Peak Stress.

Peak stress is that increment of stress which is additive to the primary plus secondary stresses by reason of local discontinuities or local thermal stress [NB-3213.13(b)] including the effects, if any, of stress concentrations. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or a brittle fracture. A stress which is not highly localized falls into this category if it is of a type which cannot cause noticeable distortion. Examples of peak stresses are:

- (a) the thermal stress in the austenitic steel cladding of a carbon steel component;
- (b) certain thermal stresses which may cause fatigue but not distortion;
- (c) the stress at a local structural discontinuity;
- (d) surface stresses produced by thermal shock.

NB-3213.12 Load Controlled Stresses.

Load controlled stresses are the stresses resulting from application of a loading, such as internal pressure, inertial loads, or the effects of gravity, whose magnitude is not reduced as a result of displacement.

NB-3213.13 Thermal Stress.

Thermal stress is a self-balancing stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally should under a change in temperature. For the purpose of establishing allowable stresses, two types of thermal stress are recognized, depending on the volume or area in which distortion takes place, as described in (a) and (b) below.

(a) General thermal stress is associated with distortion of the structure in which it occurs. If a stress of this type, neglecting stress concentrations, exceeds twice the yield strength of the material, the elastic analysis may be invalid and successive thermal cycles may produce incremental distortion. Therefore this type is classified as secondary stress in Table NB-3217-1. Examples of general thermal stresses are:

(1) stress produced by an axial temperature distribution in a cylindrical shell;

Page 70

(2) stress produced by the temperature difference between a nozzle and the shell to which it is attached;

(3) the equivalent linear stress³ produced by the radial temperature distribution in a cylindrical shell.

(b) Local thermal stress is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses shall be considered only from the fatigue standpoint and are therefore classified as local stresses in Table NB-3217-1. In evaluating local thermal stresses the procedures of NB-3227.6(b) shall be used. Examples of local thermal stresses are:

(1) the stress in a small hot spot in a vessel wall;

(2) the difference between the actual stress and the equivalent linear stress resulting from a radial temperature distribution in a cylindrical shell;

(3) the thermal stress in a cladding material which has a coefficient of expansion different from that of the base metal.

NB-3213.14 Total Stress.

Total stress is the sum of the primary, secondary, and peak stress contributions. Recognition of each of the individual contributions is essential to establishment of appropriate stress limitations.

NB-3213.15 Operational Cycle.

Operational cycle is defined as the initiation and establishment of new conditions followed by a return to the conditions which prevailed at the beginning of the cycle. The types of operating conditions which may occur are further defined in NB-3113.

NB-3213.16 Stress Cycle.

Stress cycle is a condition in which the alternating stress difference [NB-3222.4(e)] goes from an initial value through an algebraic maximum value and an algebraic minimum value and then returns to the initial value. A single operational cycle may result in one or more stress cycles. Dynamic effects shall also be considered as stress cycles.

NB-3213.17 Fatigue Strength Reduction Factor.

Fatigue strength reduction factor is a stress intensification factor which accounts for the effect of a local structural discontinuity (stress concentration) on the fatigue strength. Values for some specific cases, based on experiment, are given in NB-3338 and NB-3339. In the absence of experimental data, the theoretical stress concentration factor may be used.

³ Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

NB-3213.18 Free End Displacement.

Free end displacement consists of the relative motions that would occur between a fixed attachment and connected piping if the two members were separated and permitted to move.

NB-3213.19 Expansion Stresses.

Expansion stresses are those stresses resulting from restraint of free end displacement of the piping system.

NB-3213.20 Deformation.

Deformation of a component part is an alteration of its shape or size.

NB-3213.21 Inelasticity.

Inelasticity is a general characteristic of material behavior in which the material does not return to its original shape and size after removal of all applied loads. Plasticity and creep are special cases of inelasticity.

NB-3213.22 Creep.

Creep is the special case of inelasticity that relates to the stress-induced, time-dependent deformation under load. Small time-dependent deformations may occur after the removal of all applied loads.

NB-3213.23 Plasticity.

Plasticity is the special case of inelasticity in which the material undergoes time-independent nonrecoverable deformation.

NB-3213.24 Plastic Analysis.

Plastic analysis is that method which computes the structural behavior under given loads considering the plasticity characteristics of the materials, including strain hardening and the stress redistribution occurring in the structure.

NB-3213.25 Plastic Analysis - Collapse Load.

A plastic analysis may be used to determine the collapse load for a given combination of loads on a given structure. The following criterion for determination of the collapse load shall be used. A load-deflection or load-strain curve is plotted with load as the ordinate and deflection or strain as the abscissa. The angle that the linear part of the load-deflection or load-strain curve makes with the ordinate is called θ . A second straight line, hereafter called the collapse limit line, is drawn through the origin so that it makes an angle $\phi = \tan^{-1} (2 \tan \theta)$ with the ordinate. The collapse load is the load at the intersection of the load-deflection or load-strain curve and the collapse limit line. If this method is used, particular care should be given to ensure that the strains or deflections that are used are indicative of the load carrying capacity of the structure.

NB-3213.26 Plastic Instability Load.

The plastic instability load for members under predominantly tensile or compressive loading is defined as that load at which unbounded plastic deformation can occur without an increase in load. At the plastic tensile instability load,

Page 71

the true stress in the material increases faster than strain hardening can accommodate.

NB-3213.27 Limit Analysis.

Limit analysis is a special case of plastic analysis in which the material is assumed to be ideally plastic (nonstrain-hardening). In limit analysis, the equilibrium and flow characteristics at the limit state are used to calculate the collapse load. The two bounding methods which are used in limit analysis are the lower bound approach, which is associated with a statically admissible stress field, and the upper bound approach, which is associated with a kinematically admissible velocity field. For beams and frames, the term *mechanism* is commonly used in lieu of *kinematically admissible velocity* field.

NB-3213.28 Limit Analysis - Collapse Load.

The methods of limit analysis are used to compute the maximum load that a structure assumed to be made of ideally plastic material can carry. At this load, which is termed the collapse load, the deformations of the structure increase without bound.

NB-3213.29 Collapse Load - Lower Bound.

If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium, and nowhere exceeds the material yield strength, the load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load.

NB-3213.30 Plastic Hinge.

A plastic hinge is an idealized concept used in Limit Analysis. In a beam or a frame, a plastic hinge is formed at the point where the moment, shear, and axial force lie on the yield interaction surface. In plates and shells, a plastic hinge is formed where the generalized stresses lie on the yield surface.

NB-3213.31 Strain Limiting Load.

When a limit is placed upon a strain, the load associated with the strain limit is called the strain limiting load.

NB-3213.32 Test Collapse Load.

Test collapse load is the collapse load determined by tests according to the criteria given in II-1430.

NB-3213.33 Ratcheting.

Ratcheting is a progressive incremental inelastic deformation or strain which can occur in a component that is subjected to variations of mechanical stress, thermal stress, or both.

NB-3213.34 Shakedown.

Shakedown of a structure occurs if, after a few cycles of load application, ratcheting ceases. The subsequent structural response is elastic, or elastic-plastic, and progressive incremental inelastic deformation is absent. Elastic shakedown is the case in which the subsequent response is elastic.

NB-3213.35 Reversing Dynamic Loads.

Reversing dynamic loads (Fig. NB-3213-1) are those loads which cycle about a mean value and include building filtered loads, earthquake, and the reflected waves in a piping system due to flow transients resulting from sudden opening or closure of valves.

NB-3213.36 Nonreversing Dynamic Loads.

Nonreversing dynamic loads (Fig. NB-3213-1) are those loads which do not cycle about a mean value and include the initial thrust force due to sudden opening or closure of valves and waterhammer resulting from entrapped water in two-phase flow systems.

NB-3214 Stress Analysis

A detailed stress analysis of all major structural components shall be prepared in sufficient detail to show that each of the stress limitations of NB-3220 and NB-3230 is satisfied when the component is subjected to the loadings of NB-3110. As an aid to the evaluation of these stresses, formulas and methods for the solution of certain recurring problems have been placed in Appendix A.

NB-3215 Derivation of Stress Intensities

One requirement for the acceptability of a design (NB-3210) is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to the specified limits. The steps in the procedure are stipulated in (a) through (e) below.

(a) At the point on the component which is being investigated, choose an orthogonal set of coordinates, such as tangential, longitudinal, and radial, and designate them by the subscripts t , l , and r . The stress components in these directions are then designated σ_t , σ_l , and σ_r for direct stresses and τ_{lt} , τ_{lr} , and τ_{rt} for shear stresses.

(b) Calculate the stress components for each type of loading to which the part will be subjected, and assign each set of stress values to one or a group of the following categories:⁴

(1) general primary membrane stress P_m (NB-3213.8);

⁴ See Tables NB-3217-1 and NB-3217-2 and Note(2) of Fig. NB-3221-1.

(a) Nonreversing Dynamic Load
(Relief/Safety Valve Open End Discharge)

(b) Reversing Dynamic Load
(Earthquake Load Cycling About Normal Operating Condition)

(c) Nonreversing Followed By Reversing
(Initial Water Slug Followed By Reflected Pressure Pulses)

FIG. NB-3213-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

FIG. NB-3213-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

- (2) local primary membrane stress P_L (NB-3213.10);
 - (3) primary bending stress P_b (NB-3213.7 and NB-3213.8);
 - (4) expansion stress P_e (NB-3213.19);
 - (5) secondary stress Q (NB-3213.9);
 - (6) peak stress F (NB-3213.11). NB-3217 provides guidance for this step.
- (c) For each category, calculate the algebraic sum of the σ_i values which result from the different types of loadings and similarly for the other five stress components. Certain combinations of the categories must also be considered.
- (d) Translate the stress components for the t , l , and r directions into principal stresses σ_1 , σ_2 , and σ_3 . In many pressure component calculations, the t , l , and r directions may be so chosen that the shear stress components are zero and σ_1 , σ_2 , and σ_3 are identical to σ_t , σ_l , and σ_r .
- (e) Calculate the stress differences S_{12} , S_{23} , and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

The stress intensity S is the largest absolute value of S_{12} , S_{23} , and S_{31} .

NOTE: Membrane stress intensity is derived from the stress components averaged across the thickness of the section. The averaging shall be performed at the component level in (b) or (c) above.

NB-3216 Derivation of Stress Differences

If the specified operation of the component does not meet the conditions of NB-3222.4(d), the ability of the component to withstand the specified cyclic service without fatigue failure shall be determined as provided in NB-3222.4(e). The determination shall be made on the basis of the stresses at a point of the component, and the allowable stress cycles shall be adequate for the specified service at every point. Only the stress differences due to cyclic service loadings as specified in the Design Specification need be considered.

NB-3216.1 Constant Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do not change during the cycle, the steps stipulated in (a) through (c) below shall be taken to determine the alternating stress intensity.

(a) *Principal Stresses.* Consider the values of the three principal stresses at the point versus time for the complete stress cycle taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle. These are designated as σ_1 , σ_2 , and σ_3 for later identification.

(b) *Stress Differences.* Determine the stress differences $S_{12} = \sigma_1 - \sigma_2$, $S_{23} = \sigma_2 - \sigma_3$, and $S_{31} = \sigma_3 - \sigma_1$ versus time for the complete cycle. In what follows, the symbol S_{ij} is used to represent any one of these three stress differences.

(c) *Alternating Stress Intensity.* Determine the extremes of the range through which each stress difference S_{ij} fluctuates and find the absolute magnitude of this range for each S_{ij} . Call this magnitude S_{rij} and let $S_{alt\ ij} = 0.5S_{rij}$. The alternating stress intensity S_{alt} is the largest $S_{alt\ ij}$ value.

NB-3216.2 Varying Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do change during the stress cycle, it is necessary to use the more general procedure of (a) through (e) below.

(a) Consider the values of the six stress components σ_p , σ_b , σ_r , τ_{lp} , τ_{lr} , and τ_{rt} versus time for the complete stress cycle,

taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle.

(b) Choose a point in time when the conditions are one of the extremes for the cycle (either maximum or minimum, algebraically) and identify the stress components at this time by the subscript i . In most cases it will be possible to choose at least one time during the cycle when the conditions are known to be extreme. In some cases it may be necessary to try different points in time to find the one which results in the largest value of alternating stress intensity.

(c) Subtract each of the six stress components σ_{iP} , σ_{iR} , etc., from the corresponding stress components σ_P , σ_R , etc., at each point in time during cycle and call the resulting components σ'_P , σ'_R , etc.

(d) At each point in time during the cycle, calculate the principal stresses σ'_1 , σ'_2 , and σ'_3 derived from the six stress components σ'_P , σ'_R , etc. Note that the directions of the principal stresses may change during the cycle but each principal stress retains its identity as it rotates.

(e) Determine the stress differences $S_{12} = \sigma'_1 - \sigma'_2$, $S_{23} = \sigma'_2 - \sigma'_3$, and $S_{31} = \sigma'_3 - \sigma'_1$ versus time for the complete cycle and find the largest absolute magnitude of any stress difference at any time. The alternating stress intensity S_{alt} is one-half of this magnitude.

NB-3217 Classification of Stresses

Tables NB-3217-1 and NB-3217-2 provide assistance in the determination of the category to which a stress should be assigned.

NB-3220 STRESS LIMITS FOR OTHER THAN BOLTS

NB-3221 Design Loadings

The stress intensity limits which must be satisfied for the Design Loadings (NB-3112) stated in the Design Specifications are the four limits of this paragraph and the Special Stress Limits of NB-3227. The provisions of NB-3228 may provide relief from certain of these stress limits if plastic analysis techniques are applied. The design stress intensity values S_m are given by NB-3229. The limits are summarized by Fig. NB-3221-1.

NB-3221.1 General Primary Membrane Stress Intensity.

(Derived from P_m in Fig. NB-3221-1.) This stress intensity is derived from the average value across the thickness of a section of the general primary stresses (NB-3213.8) produced by design internal pressure and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. Averaging is to be applied to the stress components prior to determination of the stress intensity values. The allowable value of this stress intensity is S_m at the Design Temperature.

NB-3221.2 Local Membrane Stress Intensity.

(Derived from P_L in Fig. NB-3221-1.) This stress intensity is derived from the average value across the thickness of a section of the local primary stresses (NB-3213.10) produced by Design Pressure and specified Design Mechanical Loads, but excluding all thermal and peak stresses. Averaging is to be applied to the stress components prior to the determination of the stress intensity values. The allowable value of this stress intensity is $1.5S_m$.

NB-3221.3 Primary Membrane (General or Local) Plus Primary Bending Stress Intensity.

(Derived from $P_L \pm P_b$ in Fig. NB-3221-1.) This stress intensity is derived from the highest value across the thickness of a section of the general or local primary membrane stresses plus primary bending stresses produced by Design Pressure and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. For solid rectangular sections, the allowable value of this stress intensity is $1.5S_m$. For other than solid rectangular sections, a value of α times the limit established in NB-3221.1 may be used, where the factor α is defined as the ratio of the load set producing a fully plastic section to the load set producing initial yielding in the extreme fibers of the section. In the evaluation of the initial yield and fully plastic section capacities, the ratios of each individual load in the respective load set to each other

initial yield and fully plastic section capacities, the ratios of each individual load in the respective load set to each other load in that load set shall be the same as the respective ratios of the individual loads in the specified design load set. The value of α shall not exceed the value calculated for bending only ($P_m = 0$). In no case shall the value of α exceed 1.5. The propensity for buckling of the part of the section that is in compression shall be investigated. The α factor is not permitted for Level D Service Limits when inelastic component analysis is used as permitted in Appendix F.

NB-3221.4 External Pressure.

The provisions of NB-3133 apply.

NB-3222 Level A Service Limits

Level A Service Limits must be satisfied for the Service Conditions [NCA-2142.4(b)(1)] for which these limits are designated in the Design Specifications and are the four limits of this paragraph and the Special Stress Limits of NB-3227. The provisions of NB-3228 may provide relief from certain of these stress limits if plastic analysis techniques are applied. The design stress intensity values S_m are given by NB-3229. The limits are summarized by Fig. NB-3222-1.

NB-3222.1 Primary Membrane and Bending Stress Intensities.

There are no specific limits established on the primary stresses in the Level A Limits. However, the stresses due to primary loads presented during normal service must be computed and combined with the effects of other loadings in satisfying the remaining limits.

NB-3222.2 Primary Plus Secondary Stress Intensity.⁵

This stress intensity is derived from the highest value at any point across the thickness of a section of the general or local primary membrane stresses, plus primary bending stresses plus secondary stresses, produced by the specified service pressure and other specified mechanical loads and by general thermal effects associated with normal Service Conditions. The allowable value of the maximum range of this stress intensity is $3S_m$.

⁵ The concept of stress differences discussed in NB-3216 is essential to determination to the maximum range, since algebraic signs must be retained in the computation. Note that this limitation on range is applicable to the entire history of normal Service Conditions, not just to the stresses resulting from each individual transient.

**TABLE NB-3217-1
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹**

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	P_m Q
		Axial thermal gradient	Membrane Bending	Q Q
	Junction with head or flange	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section	P_m
		External load or moment	Bending across full section	P_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	P_L Q F
	Any location	Temperature difference between shell and head	Membrane Bending	Q Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	P_m P_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	P_L [Note (3)] Q
Flat head	Center region	Internal pressure	Membrane Bending	P_m P_b
	Junction to shell	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (averaged through cross section) Bending (averaged through width of ligament, but gradient through plate) Peak	P_m P_b F
	Isolated or atypical ligament	Pressure	Membrane Bending Peak	Q F F
Nozzle (NB-3227.5)	Within the limits of reinforcement defined by NB-3334	Pressure and external loads and moments, including those attributable to restrained free end displacements of attached piping	General membrane Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	P_m P_m

(continued)

TABLE NB-3217-1 CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

**TABLE NB-3217-1 (CONT'D)
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹**

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Nozzle (NB-3227.5)	Outside the limits of reinforcement defined by NB-3334	Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of attached piping	General membrane stresses	P_m
		Pressure and external loads and moments other than those attributable to restrained free end displacements of attached piping	Membrane Bending	P_L P_b
		Pressure and all external loads and moments	Membrane Bending Peak	P_L Q F
	Nozzle wall	Gross structural discontinuities	Local membrane Bending Peak	P_L Q F
		Differential expansion	Membrane Bending Peak	Q Q F
Cladding	Any	Differential expansion	Membrane Bending	F F
Any	Any	Radial temperature distribution [Note (4)]	Equivalent linear stress [Note (5)]	Q
			Nonlinear portion of stress distribution	F
Any	Any	Any	Stress concentration (notch effect)	F

NOTES:

- (1) Q & F classification of stresses refers to other than design condition (Fig. NB-3222-1).
- (2) If the bending moment at the edge is required to maintain the bending stress in the middle to acceptable limits, the edge bending is classified as P_b . Otherwise, it is classified as Q .
- (3) Consideration shall also be given to the possibility of wrinkling and excessive deformation in vessels with a large diameter-thickness ratio.
- (4) Consider possibility of thermal stress ratchet.
- (5) Equivalent linear stress if defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

TABLE NB-3217-1 (CONT'D) CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

TABLE NB-3217-2
CLASSIFICATION OF STRESS INTENSITY IN PIPING, TYPICAL CASES

Piping Component	Locations	Origin of Stress	Classification	Discontinuities Considered	
				Gross	Local
Pipe or tube, elbows, and reducers. Intersections and branch connections, except in crotch regions	Any, except crotch regions of intersections	Internal pressure	P_m P_L and Q F	No Yes Yes	No No Yes
		Sustained mechanical loads, including weight Nonreversing dynamic loads	P_o P_L and Q F	No Yes Yes	No No Yes
		Expansion	P_e F	Yes Yes	No Yes
		Axial thermal gradient Reversing dynamic loads	Q F [Note (1)]	Yes Yes Yes	No No Yes
Intersections, including tees and branch connections	In crotch region	Internal pressure, sustained mechanical loads, expansion, and nonreversing dynamic loads	P_L and Q [Note (2)] F	Yes Yes	No Yes
		Axial thermal gradient	Q F	Yes Yes	No Yes
		Reversing dynamic loads	[Note (1)]		
Bolts and flanges	Any	Internal pressure, gasket compression, and bolt load	P_m Q F	No Yes Yes	No No Yes
		Thermal gradient	Q F	Yes Yes	No Yes
		Expansion	P_e F	Yes Yes	No Yes
Any	Any	Nonlinear radial thermal gradient	F	Yes	Yes
		Linear radial thermal gradient	F	Yes	No
		Anchor point motions, including those resulting from earthquake	Q	Yes	No

NOTES:

- (1) The stress intensity resulting from this loading has special requirements that must be satisfied. For Level B Service Limits, these are provided in NB-3223(b)(2) and for Level D Service Limits in NB-3228.6.
(2) Analysis is not required when reinforced in accordance with NB-3643.

TABLE NB-3217-2 CLASSIFICATION OF STRESS INTENSITY IN PIPING, FOR SOME TYPICAL CASES

NOTES:

- (1) Bending component of primary stress for piping shall be the stress proportional to the distance from centroid of pipe cross section.
- (2) The symbols P_m , P_L , and P_b do not represent single quantities, but rather sets of six quantities representing the six stress components σ_x , σ_y , σ_z , τ_{xy} , τ_{yz} , and τ_{zx} .

FIG. NB-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR DESIGN CONDITIONS

FIG. NB-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR DESIGN CONDITIONS

FIG. NB-3222-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL A AND LEVEL B SERVICE LIMITS

NOTES:

- (1) Bending component of primary stress due to mechanical loads for piping shall be the stress proportional to the distance from centroid of pipe cross section. For piping, the calculation of P_b stresses is not required for reversing dynamic loads (including inertia earthquake effects). See NB-3223(b)(2). The symbols P_m , P_L , P_b , P_e , Q , and F do not represent single quantities, but sets of six quantities representing the six stress components σ_x , σ_y , σ_z , τ_{xy} , τ_{yz} , and τ_{zx} .
- (3) For Level B Service Limits for primary stress intensities generated by Level B Service Loadings, see NB-3223(a)(1).
- (4) When the secondary stress is due to a temperature transient at the point at which the stresses are being analyzed or to restraint of free end deflection, the value of S_m shall be taken as the average of the tabulated S_m values for the highest and the lowest temperatures of the metal during the transient. When part or all of the secondary stress is due to mechanical load, the value of S_m shall not exceed the value for the highest temperature during the transient.
- (5) Special rules for exceeding $3S_m$ are provided in NB-3228.5.
- (6) S_a is obtained from the fatigue curves, Figs. I-9.0. The allowable stress intensity for the full range of fluctuation is $2S_a$.
- (7) The stresses in category Q are those parts of the total stress that are produced by thermal gradients, structural discontinuities, etc., and they do not include primary stresses that may also exist at the same point. However, it should be noted that a detailed stress analysis frequently gives the combination of primary and secondary stresses directly and, when appropriate, the calculated value represents the total of $P_m + P_b + Q$, and not Q alone. Similarly, if the stress in category F is produced by a stress concentration, the quantity F is the additional stress produced by the notch over and above the nominal stress. For example, if a point has a nominal stress intensity P_m and has a notch with a stress concentration factor K , then $P_m \leq S_m$, $P_b = Q = 0$, $F = P_m (K - 1)$, and the peak stress intensity equals $P_m + P_m (K - 1) = KP_m$. However, P_L is the total membrane stress that results from mechanical loads, including discontinuity effects, rather than a stress increment. Therefore, the P_L value always includes the P_m contribution.

FIG. NB-3222-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL A AND LEVEL B SERVICE LIMITS (CONT'D)

[98]

FIG. NB-3222-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL A AND LEVEL B SERVICE LIMITS (CONT'D)

NB-3222.3 Expansion Stress Intensity.

(Not applicable to vessels; P_e in Fig. NB-3222-1.) This stress intensity is the highest value of stress, neglecting local structural discontinuities, produced at any point across the thickness of a section by the loadings that result from restraint of free end displacement. The allowable value of the maximum range of this stress intensity is $3S_m$.

NB-3222.4 Analysis for Cyclic Operation

(a) *Suitability for Cyclic Condition.* The suitability of a component for specified service loadings involving cyclic application of loads and thermal conditions shall be determined by the methods described herein, except that the suitability of high strength bolts shall be determined by the methods of NB-3232.3(b) and the possibility of thermal stress ratchet shall be investigated in accordance with NB-3222.5. If the specified Service Loadings of the component meet all of the conditions of (d) below, no analysis for cyclic service is required, and it may be assumed that the limits on peak stress intensities as governed by fatigue have been satisfied by compliance with the applicable requirements for material, design, fabrication, examination, and testing of this Subsection. If the Service Loadings do not meet all the conditions of (d) below, a fatigue analysis shall be made in accordance with (e) below or a fatigue test shall be made in accordance with II-1500.

(b) *Peak Stress Intensity.* This stress intensity is derived from the highest value at any point across the thickness of a section of the combination of all primary, secondary, and peak stresses produced by specified service pressures and other mechanical loads, and by general and local thermal effects associated with normal service conditions, and including the effects of gross and local structural discontinuities.

(c) *Conditions and Procedures.* The conditions and procedures of NB-3222.4 are based on a comparison of peak stresses with strain cycling fatigue data. The strain cycling fatigue data are represented by design fatigue strength curves of Figs. I-9.0. These curves show the allowable amplitude S_a of the alternating stress intensity component (one-half of the alternating stress intensity range) plotted against the number of cycles. This stress intensity amplitude is calculated on the assumption of elastic behavior and, hence, has the dimensions of stress, but it does not represent a real stress when the elastic range is exceeded. The fatigue curves are obtained from uniaxial strain cycling data in which the imposed strains have been multiplied by the elastic modulus and a design margin has been provided so as to make the calculated stress intensity amplitude and the allowable stress intensity amplitude directly comparable.⁶ Where necessary, the curves have been adjusted to include the maximum effects of mean stress, which is the condition where the stress fluctuates about a mean value that is different from zero. As a consequence of this procedure, it is essential that the requirements of NB-3222.2 be satisfied at all times with transient stresses included, and that the calculated value of the alternating stress intensity be proportional to the actual strain amplitude. To evaluate the effect of alternating stresses of varying amplitudes, a linear damage relation is assumed in (e)(4) below.

(d) *Components Not Requiring Analysis for Cyclic Service.* An analysis for cyclic service is not required, and it may be assumed that the limits on peak stress intensities as governed by fatigue have been satisfied for a component by compliance with the applicable requirements for material, design, fabrication, examination, and testing of this Subsection, provided the specified Service Loading⁷ of the component or portion thereof meets all the conditions stipulated in (1) through (6) below.

(1) *Atmospheric to Service Pressure Cycle.* The specified number of times (including startup and shutdown) that the pressure will be cycled from atmospheric pressure to service pressure and back to atmospheric pressure during normal service does not exceed the number of cycles on the applicable fatigue curve of Figs. I-9.0 corresponding to an S_a value of three times the S_m value for the material at service temperature.

⁶ As an exception to the use of strain controlled test data, Fig. I-9.2.2, Curves B and C are based on load controlled fatigue data.

⁷ As is stated in NB-3223, for components operating within the temperature limits of this Subsection, Service Loadings for which Level B Limits are designed must be considered as though Level A Limits were designated in evaluating exemptions from fatigue analysis.

(2) *Normal Service Pressure Fluctuation.* The specified full range of pressure fluctuations during normal service does not exceed the quantity $\frac{1}{3} \times \text{Design Pressure} \times (S_d/S_m)$, where S_d is the value obtained from the applicable design fatigue curve for the total specified number of significant pressure fluctuations and S_m is the allowable stress intensity for the material at service temperature. If the total specified number of significant pressure fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_d value corresponding to the maximum number of cycles defined on the curve may be used. Significant pressure fluctuations are those for which the total excursion exceeds the quantity:

$$\text{Design Pressure} \times \frac{1}{3} \times (S/S_m)$$

where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(3) *Temperature Difference - Startup and Shutdown.* The temperature difference, °F, between any two adjacent points⁸ of the component during normal service does not exceed $S_d/2E\alpha$, where S_d is the value obtained from the applicable design fatigue curves for the specified number of startup-shutdown cycles, α is the value of the instantaneous coefficient of thermal expansion and E at the mean value of the temperatures at the two points as given by Section II, Part D, Subpart 2, Tables TE and TM.

(4) *Temperature Difference - Normal Service.*⁹ The temperature difference, °F, between any two adjacent points⁸ does not change¹⁰ during normal service by more than the quantity $S_d/2E\alpha$, where S_d is the value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant temperature difference fluctuations. A temperature difference fluctuation shall be considered to be significant if its total algebraic range exceeds the quantity $S/2E\alpha$, where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

⁸ Adjacent points are defined in (a), (b), and (c) below.

(a) For surface temperature differences on surfaces of revolution in the meridional direction, adjacent points are defined as points that are less than the distance $2\sqrt{Rt}$, where R is the radius measured normal to the surface from the axis of rotation to the midwall and t is the thickness of the part at the point under consideration. If the product Rt varies, the average value of the points shall be used.

(b) For surface temperature differences on surfaces of revolution in the circumferential direction and on flat parts, such as flanges and flat heads, adjacent points are defined as any two points on the same surface.

(c) For through-thickness temperature differences, adjacent points are defined as any two points on a line normal to any surface.

⁹ Normal service is defined as service, other than startup and shutdown, resulting in specified Service Loadings for which Level A Limits, Level B Limits, or Testing Limits are designated.

¹⁰ The algebraic range of the difference shall be used.

(5) *Temperature Difference - Dissimilar Materials.* For components fabricated from materials of differing moduli of elasticity or coefficients of thermal expansion, the total algebraic range of temperature fluctuation, °F, experienced by the component during normal service does not exceed the magnitude $S_d/2(E_1\alpha_1 - E_2\alpha_2)$, where S_d is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature fluctuations, E_1 and E_2 are the moduli of elasticity, and α_1 and α_2 are the values of the instantaneous coefficients of thermal expansion at the mean temperature value involved for the two materials of construction given in Section II, Part D, Subpart 2, Tables TE and TM. A temperature fluctuation shall be considered to be significant if its total excursion exceeds the quantity $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the

applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve. If the two materials used have different applicable design fatigue curves, the lower value of S_a shall be used in applying the rules of this paragraph.

(6) *Mechanical Loads.* The specified full range of mechanical loads, excluding pressure but including pipe reactions, does not result in load stresses whose range exceeds the S_a value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant load fluctuations. If the total specified number of significant load fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_a value corresponding to the maximum number of cycles defined on the curve may be used. A load fluctuation shall be considered to be significant if the total excursion of load stress exceeds the quantity S , where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(e) *Procedure for Analysis for Cyclic Loading.* If the specified Service Loadings for the component do not meet the conditions of NB-3222.4(d), the ability of the component to withstand the specified cyclic service without fatigue failure shall be determined as provided in this subsubparagraph. The determination shall be made on the basis of the stresses at a point, and the allowable stress cycles shall be adequate for the specified Service Loadings at every point. Only

Page 83

the stress differences due to service cycles as specified in the Design Specifications need be considered. Compliance with these requirements means only that the component is suitable from the standpoint of possible fatigue failure; complete suitability for the specified Service Loadings is also dependent on meeting the general stress limits of NB-3222 and any applicable special stress limits of NB-3227.

(1) *Stress Differences.* For each condition of normal service, determine the stress differences and the alternating stress intensity S_a in accordance with NB-3216.

(2) *Local Structural Discontinuities.* These effects shall be evaluated for all conditions using stress concentration factors determined from theoretical, experimental, or photoelastic studies, or numerical stress analysis techniques. Experimentally determined fatigue strength reduction factors may be used when determined in accordance with the procedures of II-1600, except for high strength alloy steel bolting for which the requirements of NB-3232.3(c) shall apply when using the design fatigue curve of Fig. I-9.4. Except for the case of crack-like defects and specified piping geometries for which specific values are given in NB-3680, no fatigue strength reduction factor greater than five need be used.

(3) *Design Fatigue Curves.* Figures I-9.0 contain the applicable fatigue design curves for the materials permitted by this Subsection. When more than one curve is presented for a given material, the applicability of each is identified. Where curves for various strength levels of a material are given, linear interpolation may be used for intermediate strength levels of these materials. The strength level is the specified minimum room temperature value. The design fatigue curves of Figs. I-9.0 are defined over a cyclic range of 10 to 10^6 cycles, except that for austenitic steels, nickel-chromium-iron alloys, and nickel-iron-chromium alloys, nickel-chromium-molybdenum-iron alloys, and nickel-copper alloys, the design fatigue curve is extended to 10^{11} cycles in Figs. I-9.2.2 and I-9.5. Criteria for the use of the latter curve are given in Fig. I-9.2.2 and are also presented graphically by the flow chart given in Fig. I-9.2.3.

(4) *Effect of Elastic Modulus.* Multiply S_{alt} (as determined in NB-3216.1 or NB-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve of Figs. I-9.0 at this value on the ordinate axis and find the corresponding number of cycles on the abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(5) *Cumulative Damage.* If there are two or more types of stress cycle which produce significant stresses, their cumulative effect shall be evaluated as stipulated in Steps 1 through 6 below.

Step 1: Designate the specified number of times each type of stress cycle of types 1, 2, 3, ..., n , will be repeated during the life of the component as $n_1, n_2, n_3, \dots, n_n$ respectively.

NOTE: In determining $n_1, n_2, n_3, \dots, n_n$ consideration shall be given to the superposition of cycles of various origins which produce a total stress difference range greater than the stress difference ranges of the individual cycles. For example, if one type of stress cycle produces 1000 cycles of a stress difference variation from zero to +60,000 psi and another type of stress cycle produces 10,000 cycles of a stress difference variation from zero to -50,000 psi, the two types of cycle to be considered are defined by the following parameters:

(a) for type 1 cycle, $n_1 = 1000$ and $S_{alt 1} = (60,000 + 50,000)/2 = 55,000$ psi;

(b) for type 2 cycle, $n_2 = 9000$ and $S_{alt 2} = (50,000 + 0)/2 = 25,000$ psi.

Step 2: For each type of stress cycle, determine the alternating stress intensity S_{alt} by the procedures of NB-3216.1 or NB-3216.2 above. Call these quantities $S_{alt 1}, S_{alt 2}, S_{alt 3}, \dots, S_{alt n}$

Step 3: For each value $S_{alt 1}, S_{alt 2}, S_{alt 3}, \dots, S_{alt n}$ use the applicable design fatigue curve to determine the maximum number of repetitions which would be allowable if this type of cycle were the only one acting. Call these values $N_1, N_2, N_3, \dots, N_n$

Step 4: For each type of stress cycle, calculate the usage factors $U_1, U_2, U_3, \dots, U_n$ from $U_1 = n_1/N_1, U_2 = n_2/N_2, U_3 = n_3/N_3, \dots, U_n = n_n/N_n$

Step 5: Calculate the cumulative usage factor U from $U = U_1 + U_2 + U_3 + \dots + U_n$

Step 6: The cumulative usage factor U shall not exceed 1.0.

NB-3222.5 Thermal Stress Ratchet.

It should be noted that under certain combinations of steady state and cyclic loadings there is a possibility of large distortions developing as the result of ratchet action; that is, the deformation increases by a nearly equal amount for each cycle. Examples of this phenomenon are treated in this subparagraph and in NB-3227.3.

(a) The limiting value of the maximum cyclic thermal stress permitted in a portion of an axisymmetric shell loaded by steady state internal pressure in order to prevent cyclic growth in diameter is as follows. Let

x	= maximum general membrane stress due to pressure divided by the yield strength S_y
-----	---

Page 84

y'	= maximum allowable range of thermal stress computed on an elastic basis divided by the yield strength ¹¹ S_y
------	--

Case 1: Linear variation of temperature through the wall: for $0 < x < 0.5, y' = 1/x$ and, for $0.5 < x < 1.0, y' = 4(1-x)$.

Case 2: Parabolic constantly increasing or constantly decreasing variation of temperature through the wall: for $0.615 < x < 1.0, y' = 5.2(1-x)$ and, approximately for $x < 0.615, y' = 4.65, 3.55, \text{ and } 2.70$ for $x = 0.3, 0.4, \text{ and } 0.5$, respectively.

(b) Use of yield strength S_y in the above relations instead of the proportional limit allows a small amount of growth during each cycle until strain hardening raises the proportional limit to S_y . If the yield strength of the material is higher than the endurance limit¹² for the material, the latter value shall be used if there is to be a large number of cycles because strain softening may occur.

NB-3222.6 Deformation Limits.

Any deformation limits prescribed by the Design Specifications shall be satisfied.

[98]

NB-3223 Level B Service Limits

(a) For components other than piping operating within the temperature limits of this Subsection, the requirements of (1), (2), and (3) below shall apply.

(1) The values of Level A Service Limits shall apply for Level B Service Limits, except that for primary stress intensities generated by Level B Service Loadings, allowable stress intensity values of 110% of those given in Fig. NB-3221-1 shall apply.

(2) In evaluating possible exemption from fatigue analysis by the methods of NB-3222.4(d), Service Loadings for which Level B Limits are designated shall be considered as though Level A Limits were designated.

(3) Any deformation limits prescribed by the Design Specifications shall be satisfied.

(b) For piping components operating within the temperature limits of this Subsection, the requirements of (1) or (2) below shall apply.

11 It is permissible to use $1.5S_m$ whenever it is greater than S_y .

12 The endurance limit shall be taken as two times the S_a value at 10^7 cycles in the applicable fatigue curve of Figs. I-9.0, except that for the curves of Figs. I-9.2.1 and I-9.2.2 the endurance limit shall be taken as two times the S_a value at 10^{11} cycles obtained from Curve A.

(1) For Level B Service Limits which do not include reversing dynamic loads (NB-3213.35) or have reversing dynamic loads combined with nonreversing dynamic loads (NB-3213.36), the requirements of (a)(1), (a)(2), and (a)(3) above shall be satisfied.

(2) For Level B Service Limits which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of NB-3222.2 and NB-3222.4(e) shall be satisfied in lieu of (b)(1) above. In addition, any deflection limits prescribed by the Design Specification must be satisfied.

[98]

NB-3224 Level C Service Limits

If the Design Specifications specify any Service Loadings for which Level C Service Limits are designated [NCA-2142.4(b)(3) and NB-3113(b)] for components other than piping, the rules used in evaluating these loadings shall be those used for other loadings, except as modified by the following subparagraphs and as summarized in Fig. NB-3224-1. For piping, special requirements are provided in NB-3224.7.

NB-3224.1 Primary Stress Limits.

The primary stress limits of NB-3221 shall be satisfied using an S_m value equal to the greater of 120% of the tabulated S_m value or 100% of the tabulated yield strength, with both values taken at the appropriate temperature. In addition, for ferritic material, the P_m elastic analysis limits for pressure loadings alone shall be equal to the greater of $1.1S_m$ or $0.9S_y$.

NB-3224.2 External Pressure.

The permissible external pressure shall be taken as 120% of that given by the rules of NB-3133.

NB-3224.3 Special Stress Limits.

The permissible values for special stress limit shall be taken as 120% of the values given in NB-3227.4 and NB-3228.

NB-3224.4 Secondary and Peak Stresses.

The requirements of NB-3222.2, NB-3222.4, NB-3222.5, and NB-3227.3 need not be satisfied.

NB-3224.5 Fatigue Requirements.

Service Loadings for which Level C Service Limits are designated need not be considered when applying the procedures of NB-3222.4(a) to determine whether or not a fatigue analysis is required.

NB-3224.6 Deformation Limits.

Any deformation limits prescribed by the Design Specifications shall be considered.

NB-3224.7 Piping Requirements

(a) For Level C Service Limits which do not include reversing dynamic loads or have reversing dynamic load combined with nonreversing dynamic loads, the

Page 85

requirements of NB-3224.1 through NB-3224.6 above shall be satisfied.

NOTES:

- (1) The symbols P_m , P_l , P_b , Q , and F do not represent single quantities, but rather sets of six quantities representing the six stress components σ_1 , σ_2 , σ_3 , τ_{xy} , τ_{yz} , and τ_{zx} .
- (2) For configurations where compressive stresses occur, the stress limits shall be revised to take into account critical buckling stresses [NB-3211(c)].
- (3) The limits shown are for stresses resulting from pressure in combination with other mechanical loads. For ferritic materials, the P_1 elastic analysis limits for pressure loadings alone shall be equal to the greater of $1.15S_m$ or $0.9S_v$.
- (4) C_1 the collapse load calculated on the basis of the lower bound theorem of limit analysis and yield strength values specified in Section II, Part D, Subpart 2, Table Y-1.
- (5) The triaxial stresses represent the algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) for the combination of stress components.
- (6) For piping, alternative requirements are provided in NB-3224.7.

* Use the greater of the values specified.

FIG. NB-3224-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL C SERVICE LIMITS

FIG. NB-3224-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL C SERVICE LIMITS

(b) As an alternative to (a) above, for Level C Service Limits which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of NB-3228.6 may be satisfied using 70% of the specified allowable strain values.

NB-3225 Level D Service Limits

(a) For components other than piping, if the Design Specifications specify any Service Loadings for which Level D Limits are designated [NCA-2142.4(b)(4)], the rules contained in Appendix F may be used in evaluating these loadings, independently of all other Design and Service Loadings.

(b) For piping fabricated from material designated P-No. 1 through P-No. 9 in Table 2A, Section II, Part D, if the Design Specifications specify any Service Loading for which Level D Limits are designated [NCA-2142.4(b)(4)], the rules contained in NB-3228.6 may be used as an alternative to those contained in Appendix F. For other piping materials, the rules of Appendix F may be used in evaluating these loadings, independently of all other Design and Service Loadings.

NB-3226 Testing Limits

The evaluation of pressure test loadings (NCA-2142.3) shall be in accordance with (a) through (e) below, except that these rules do not apply to the items in NB-3500.

(a) The general primary membrane stress intensity P_m shall not exceed 90% of the tabulated yield strength S_y at test temperature.

(b) The primary membrane plus bending stress intensity $P_m + P_b$ shall not exceed the applicable limits given in (1) or (2) below.

(1) For $P_m \leq 0.67S_y$

$$P_m + P_b \leq 1.35S_y$$

(2) For $0.67S_y < P_m \leq 0.90S_y$

$$P_m + P_b \leq (2.15S_y - 1.2P_m)$$

where S_y is the tabulated yield strength at test temperature.

(c) The external pressure shall not exceed 135% of the value determined by the rules of NB-3133. Alternatively, an external hydrostatic test pressure may be applied up to a maximum of 80% of the lower of the collapse or elastic instability pressures determined by analysis or experimental procedures (NB-3228 and Appendix II) including consideration of allowable tolerances. If a collapse analysis is performed, it shall be a lower bound limit analysis assuming ideally elastic-plastic (nonstrain-hardening) material having a yield strength equal to its tabulated yield strength at test temperature.

(d) For the 1.25 Design Pressure hydrostatic test of NB-6221, or the 1.20 to 1.25 Design Pressure pneumatic tests of NB-6321, the stresses shall be calculated and compared to the limits of (a), (b), and (c) above. This calculation and the fatigue evaluation of (e) below need not be revised unless the actual hydrostatic test pressure of NB-6221 exceeds the 1.25 Design Pressure by more than 6%, or the actual pneumatic test pressure of NB-6321 exceeds 1.25 Design Pressure.

(e) Tests, with the exception of either the first 10 hydrostatic tests in accordance with NB-6220, the first 10 pneumatic tests in accordance with NB-6320, or any combination of 10 such tests, shall be considered in the fatigue evaluation of the component. In this fatigue evaluation, the limits on the primary plus secondary stress intensity range (NB-3222.2) may be taken as the larger of $3S_m$ or $2S_y$ when at least one extreme of the stress intensity range is determined by the Test Loadings.

NB-3227 Special Stress Limits

The following deviations from the basic stress limits are provided to cover special Service Loadings or configurations. Some of these deviations are more restrictive, and some are less restrictive, than the basic stress limits. In cases of conflict between these requirements and the basic stress limits, the rules of NB-3227 take precedence for the particular situations to

which they apply.

NB-3227.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, except those for which Level D Limits are designated, shall be limited to S_y at temperature, except that when the distance to a free edge is larger than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted. For clad surfaces, the yield strength of the base metal may be used if, when calculating the bearing stress, the bearing area is taken as the lesser of the actual contact area

Page 87

or the area of the base metal supporting the contact surface.

(b) When bearing loads are applied near free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. In the case of load stress only (NB-3213.12) the average shear stress shall be limited to $0.6S_m$. In the case of load stress plus secondary stress (NB-3213.10) the average shear stress shall not exceed (1) or (2) below:

(1) for materials to which Note (2) of Section II, Part D, Subpart 1, Tables 2A and 2B applies, the lower of $0.5S_y$ at 100°F (38°C) and $0.675S_y$ at temperature;

(2) for all other materials, $0.5S_y$ at temperature.

For clad surfaces, if the configuration or thickness is such that a shear failure could occur entirely within the clad material, the allowable shear stress for the cladding shall be determined from the properties of the equivalent wrought material. If the configuration is such that a shear failure could occur across a path that is partially base metal and partially clad material, the allowable shear stresses for each material shall be used when evaluating the combined resistance to this type of failure.

(c) When considering bearing stresses in pins and similar members, the S_y at temperature value is applicable, except that a value of $1.5S_y$ may be used if no credit is given to bearing area within one pin diameter from a plate edge.

NB-3227.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, except those for which Level D Limits are designated (for example, keys, shear rings, screw threads), shall be limited to $0.6S_m$.

(b) The maximum primary shear that is experienced as a result of Design Loadings, Test Loadings, or any Service Loadings (except those for which Level D Limits are designated), exclusive of stress concentration, at the periphery of a solid circular section in torsion shall be limited to $0.8S_m$. Primary plus secondary and peak shear stresses shall be converted to stress intensities (equal to two times the pure shear stress) and as such shall not exceed the basic stress limits of NB-3222.2 and NB-3222.4.

[98]

NB-3227.3 Progressive Distortion of Nonintegral Connections.

Screwed on caps, screwed in plugs, shear ring closures, and breech lock closures are examples of nonintegral connections which are subject to failure by bell mousing or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete operating cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can eventually lose engagement. Therefore, primary plus secondary stress intensities (NB-3222.2), which result in slippage between the parts of a nonintegral connection in which disengagement could occur as a result of progressive distortion, shall be limited to the value S_y (Section II, Part D, Subpart 1, Table Y-1).

[98]

NB-3227.4 Triaxial Stresses.

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_m , except for Service Level D.

NB-3227.5 Nozzle Piping Transition.

Within the limits of reinforcement given by NB-3334, whether or not nozzle reinforcement is provided, the P_m classification is applicable to stress intensities resulting from pressure-induced general membrane stresses as well as stresses other than discontinuity stresses due to external loads and moments including those attributable to restrained free end displacements of the attached pipe. Also, within the limits of reinforcement, a P_L classification shall be applied to local primary membrane stress intensities derived from discontinuity effects plus primary bending stress intensities due to combined pressure and external loads and moments, including those attributable to restrained free end displacements of the attached pipe; and a $P_L + P_b + Q$ classification shall apply to primary plus secondary stress intensities resulting from a combination of pressure, temperature, and external loads and moments, including those due to restrained free end displacements of the attached pipe. Beyond the limits of reinforcement, a P_m classification is applicable to stress intensities resulting from pressure-induced general membrane stresses as well as the average stress across the nozzle thickness due to externally applied nozzle axial, shear, and torsional loads other than those attributable to restrained free end displacement of the attached pipe. Also, outside the limits of reinforcement a $P_L + P_b$ classification is applicable to the stress intensities that result from adding those stresses classified as P_m to those due to externally applied bending moments, except those attributable to restrained free end displacement of the pipe. Further, beyond the limits of reinforcement, a $P_L + P_b + Q$ classification is applicable to stress intensities resulting from all pressure, temperature, and external loads and moments, including those attributable to restrained free end displacements of the attached pipe. Beyond the

Page 88

limits of reinforcement, the $3S_m$ limit on the range of primary plus secondary stress intensity may be exceeded as provided in NB-3228.5, except that in the evaluation of NB-3228.5(a) stresses from restrained free end displacements of the attached pipe may also be excluded. The range of membrane plus bending stress intensity attributable solely to the restrained free end displacements of the attached pipe shall be $\leq 3S_m$. The nozzle, outside the reinforcement limit, shall not be thinner than the larger of the pipe thickness or the quantity $t_p(S_{mp}/S_{mn})$, where t_p is the nominal thickness of the mating pipe, S_{mp} is the allowable stress intensity value for the pipe material, and S_{mn} is the allowable stress intensity value for the nozzle material.

NB-3227.6 Applications of Elastic Analysis for Stresses Beyond the Yield Strength.

Certain of the allowable stresses permitted in the design criteria are such that the maximum stress calculated on an elastic basis may exceed the yield strength of the material. The limit on primary plus secondary stress intensity of $3S_m$ (NB-3222.2) has been placed at a level which ensures shakedown to elastic action after a few repetitions of the stress cycle except in regions containing significant local structural discontinuities or local thermal stresses. These last two factors are considered only in the performance of a fatigue evaluation. Therefore:

(a) In evaluating stresses for comparison with the stress limits on other than fatigue allowables, stresses shall be calculated on an elastic basis.

(b) In evaluating stresses for comparison with fatigue allowables, all stresses except those which result from local thermal stresses [NB-3213.13(b)] shall be evaluated on an elastic basis. In evaluating local thermal stresses, the elastic equations shall be used, except that the numerical value substituted for Poisson's ratio shall be determined from the expression:

$$\nu = 0.5 - 0.2 (S_y/S_a), \text{ but not less than } 0.3$$

where

S_a = value obtained from the applicable design fatigue curve (Figs. I-9.0) for the specified number of cycles of the condition being considered

S_y = yield strength of the material at the mean value of the temperature of the cycle

NB-3227.7 Requirements for Specially Designed Welded Seals

(a) Welded seals, such as omega and canopy seals (NB-4360), shall be designed to meet the pressure induced general primary membrane stress intensity limits specified in this Subsection. Note that the general primary membrane stress intensity varies around the toroidal cross section.

(b) All other membrane and bending stress intensities developed in the welded seals may be considered as secondary stress intensities. The range of these stress intensities combined with the general primary membrane stress intensity may exceed the primary plus secondary stress intensity limit of $3S_m$ if they are analyzed in accordance with NB-3228.5 as modified in (1) and (2) below.

(1) In lieu of NB-3228.5(a), the range of the combined primary plus secondary membrane stress intensities shall be $\leq S_m$.

(2) NB-3228.5(d) need not apply.

NB-3228 Applications of Plastic Analysis

The following subparagraphs provide guidance in the application of plastic analysis and some relaxation of the basic stress limits which are allowed if plastic analysis is used.

[98]

NB-3228.1 Limit Analysis.

The limits on General Membrane Stress Intensity (NB-3221.1), Local Membrane Stress Intensity (NB-3221.2), and Primary Membrane Plus Primary Bending Stress Intensity (NB-3221.3) need not be satisfied at a specific location if it can be shown by limit analysis that the specified loadings do not exceed two-thirds of the lower bound collapse load. The yield strength to be used in these calculations is $1.5S_m$. The use of $1.5S_m$ for the yield strength of those materials of Section II, Part D, Subpart 1, Tables 2A and 2B to which Note (2) of the Table is applicable may result in small permanent strains during the first few cycles of loading. If these strains are not acceptable, the yield strength to be used shall be reduced according to the strain limiting factors of Section II, Part D, Subpart 1, Table Y-2. When two-thirds of the lower bound collapse load is used, the effects of plastic strain concentrations in localized areas of the structure such as the points where hinges form must be considered. The effects of these concentrations of strain on the fatigue behavior, ratcheting behavior, or buckling behavior of the structure must be considered in the design. The design shall satisfy the minimum wall thickness requirements.

[98]

NB-3228.2 Experimental Analysis.

The limits of General Primary Membrane Stress Intensity (NB-3221.1), Local Membrane Stress Intensity (NB-3221.2), and Primary Membrane Plus Primary Bending Stress Intensity (NB-3221.3) need not be satisfied at a specific location if it can be shown that the specified loadings do not exceed two-thirds of the test collapse load

Page 89

determined by application of II-1430, in which case the effects of plastic strain concentrations in localized areas of the structure, such as the points where hinges form, must be considered. The effects of these concentrations of strain on the fatigue behavior, ratcheting behavior, or buckling behavior of the structure must be considered in the design. The design shall satisfy the minimum wall thickness requirements.

NB-3228.3 Plastic Analysis.

Plastic analysis is a method of structural analysis by which the structural behavior under given loads is computed by considering the actual material stress-strain relationship and stress redistribution, and it may include either strain hardening or change in geometry, or both.

The limits of General Membrane Stress Intensity (NB-3221.1), Local Membrane Stress Intensity (NB-3221.2), and Primary Membrane Plus Primary Bending Stress Intensity (NB-3221.3) need not be satisfied at a specific location if it

can be shown that the specified loadings do not exceed two-thirds of the plastic analysis collapse load determined by application of II-1430 to a load-deflection or load-strain relationship obtained by plastic analysis. When this rule is used, the effects of plastic strain concentrations in localized areas of the structure, such as the points where hinges form, must be considered. The effects of the concentrations of strain on the fatigue behavior, ratcheting behavior, or buckling behavior of the structure must be considered in the design. The design shall satisfy the minimum wall thickness requirements.

NB-3228.4 Shakedown Analysis.

The limits on Thermal Stress Ratchet in Shell (NB-3222.5) and Progressive Distortion of Non-Integral Connections (NB-3227.3) need not be satisfied at a specific location, if, at the location, the procedures of (a) through (c) below are used.

(a) In evaluating stresses for comparison with the remaining stress limits, the stresses shall be calculated on an elastic basis.

(b) In lieu of satisfying the specific requirements of NB-3221.2, NB-3222.2, NB-3222.5, and NB-3227.3 at a specific location, the structural action shall be calculated on a plastic basis, and the design shall be considered to be acceptable if shakedown occurs (as opposed to continuing deformation). However, this shakedown requirement need not be satisfied for materials having a minimum specified yield strength to specified minimum ultimate strength ratio of less than 0.70 provided the maximum accumulated local strain at any point, as a result of cyclic operation to which plastic analysis is applied, does not exceed 5.0%. In all cases, the deformations which occur shall not exceed specified limits.

**TABLE NB-3228.5(b)-1
VALUES OF m , n , AND $T_{\max}$ FOR VARIOUS
CLASSES OF PERMITTED MATERIALS**

Materials	m	n	$T_{\max}$ /° F
Carbon steel	3.0	0.2	700
Low alloy steel	2.0	0.2	700
Martensitic stainless steel	2.0	0.2	700
Austenitic stainless steel	1.7	0.3	800
Nickel-chromium-iron	1.7	0.3	800
Nickel-copper	1.7	0.3	800

TABLE NB-3228.5(b)-1 VALUES OF m , n , AND $T_{\max}$ FOR VARIOUS CLASSES OF PERMITTED MATERIALS

(c) In evaluating stresses for comparison with fatigue allowables, the numerically maximum principal total strain range shall be multiplied by one-half the modulus of elasticity of the material (Section II, Part D, Subpart 2, Tables TM) at the mean value of the temperature of the cycle.

NB-3228.5 Simplified Elastic-Plastic Analysis.

The $3S_m$ limit on the range of primary plus secondary stress intensity (NB-3222.2) may be exceeded provided that the requirements of (a) through (f) below are met.

(a) The range of primary plus secondary membrane plus bending stress intensity, excluding thermal bending stresses, shall be $\leq 3S_m$.

(b) The value of S_a used for entering the design fatigue curve is multiplied by the factor K_e where:

$$\begin{aligned} K_e &= 1.0, \text{ for } S_n \leq 3S_m \\ &= 1.0 + [(1 - n)/n(m - 1)]S_n/3S_m - 1, \text{ for } 3S_m < S_n < 3mS_m \\ &= 1/n, \text{ for } S_n \geq 3mS_m \\ S_n &= \text{range of primary plus secondary stress intensity, psi} \end{aligned}$$

The values of the material parameters m and n for the various classes of permitted materials are as given in Table NB-3228.5(b)-1.

(c) The rest of the fatigue evaluation stays the same as required in NB-3222.4, except that the procedure of NB-3227.6 need not be used.

(d) The component meets the thermal ratcheting requirement of NB-3222.5.

(e) The temperature does not exceed those listed in Table NB-3228.5(b)-1 for the various classes of materials.

(f) The material shall have a specified minimum yield strength to specified minimum tensile strength ratio of less than 0.80.

Page 90

NB-3228.6 Reversing Dynamic Loading in Piping.

For piping fabricated from material designated P-No. 1 through P-No. 9 in Table 2A, Section II, Part D, if the Design Specifications specify any Service Loading for which Level D limits are designated [NCA-2142.2(b)(4)], the rules contained in NB-3228.6 may be used as an alternative to those contained in Appendix F. For other piping materials, the rules of Appendix F may be used in evaluating these loadings, independently of all other Design and Service Loadings. As an alternative to meeting the requirements of Appendix F, for piping components subjected to reversing type dynamic loading as defined in NB-3213.35, the requirements of (a)(1) and (a)(2) below shall be satisfied. However, when the specified Level D Load combination includes nonreversing dynamic loads (NB-3213.36) alone or coincident with earthquake and other reversing dynamic loads for which the Design Specification requires satisfaction of Level D Service Limits, the requirements of Appendix F must be satisfied for Level D.

(a) Deflections, deformations, and strains, including those caused by incremental ratcheting, must be evaluated on an inelastic basis to assure compliance with these limits.

(1) The effective ratchet strain averaged through the wall thickness of the piping component due to the application of all simultaneously applied loading including pressure, the effects of gravity, thermal expansion ranges, earthquake inertia ranges, anchor motion ranges, (including thermal, earthquake, etc.) and reversing dynamic loading ranges shall not exceed 5%.

(2) The effective local peak cyclic single-amplitude strain ϵ_{ar} in the wall of the piping component due to the application of all simultaneously applied loading ranges considered in (a)(1) above shall not exceed the following.

$$\epsilon_{an} \leq \frac{S_{a10}}{(E\sqrt{N})}$$

where

the *equivalent strain range* is defined as follows.

Step 1: Identify all strain components for each point, i , in time (ϵ_{xp} ϵ_{yp} ϵ_{zp} Γ_{xyp} Γ_{yzp} Γ_{zxp}) for a complete cycle of interest.

Step 2: Select a time point when conditions are at an extreme for the cycle, either maximum or minimum. Refer to this time point as o .

Step 3: Calculate the history of the change in strain components by subtracting the values at the time, o , from the corresponding components at each point in time, i , during the cycle.

$$\delta\epsilon_{xi} = \epsilon_{xi} - \epsilon_{xo}$$

$$\delta\epsilon_{yi} = \epsilon_{yi} - \epsilon_{yo}$$

etc.

Step 4: Calculate the equivalent strain ranges for each point in time as:

$$\delta\epsilon_{equiv.i} = \frac{\sqrt{2}}{3} \left[(\delta\epsilon_{xi} - \delta\epsilon_{yi})^2 + (\delta\epsilon_{yi} - \delta\epsilon_{zi})^2 + (\delta\epsilon_{zi} - \delta\epsilon_{xi})^2 + \frac{3}{2} (\delta\Gamma_{xyi}^2 + \delta\Gamma_{yzi}^2 + \delta\Gamma_{zxi}^2) \right]^{1/2}$$

Step 5: The *equivalent strainrange* is the maximum value of the above calculated equivalent strain ranges, $\delta\epsilon_{equiv.i}$. The *effective cyclic single-amplitude strain* is half the equivalent strain range for one typical cycle of loading. The *equivalent ratchet strain* is the value of the above calculated equivalent strain range over all the cycles of loading.

E = Young's Modulus

N = 10 for earthquake event. For other reversing dynamic loads N is the number of cycles defined in the Design Specification. However, N can never be taken as less than 10.

S_{a10} = The S_a value at 10 cycles from the applicable Design Fatigue Curve in Appendix I

[98]

NB-3229 Design Stress Values

The design stress intensity values S_m are given in Section II, Part D, Subpart 1, Tables 2A and 2B for component materials. Values for intermediate temperatures may be found by interpolation. These form the basis for the various stress limits. Values of yield strength are given in Section II, Part D, Subpart 1, Table Y-1. Values of the coefficient of thermal expansion and modulus of elasticity are in Section II, Part D, Subpart 2, Tables TE and TM. The basis for establishing stress values is given in Appendix III. The design fatigue curves used in conjunction with NB-3222.4 are those of Figs. I-9.0.

[98]

NB-3230 STRESS LIMITS FOR BOLTS

NB-3231 Design Conditions

(a) The number and cross-sectional area of bolts required to resist the Design Pressure shall be determined in accordance

with the procedures of Appendix E, using the larger of the bolt loads, given by the equations of Appendix E, as a Design Mechanical Load. The allowable bolt design stresses shall be the values given in Section II, Part D, Subpart 1, Table 4 for bolting material.

(b) When sealing is effected by a seal weld instead of a gasket, the gasket factor m and the minimum design seating stress y may be taken as zero.

(c) When gaskets are used for preservice testing only, the design is satisfactory if the above requirements are satisfied for $m=y=0$, and the requirements of NB-3232 are satisfied when the appropriate m and y factors are used for the test gasket.

NB-3232 Level A Service Limits

Actual service stresses in bolts, such as those produced by the combination of preload, pressure, and differential thermal expansion, may be higher than the values given in Section II, Part D, Subpart 1, Table 4.

NB-3232.1 Average Stress.

The maximum value of service stress, averaged across the bolt cross section and neglecting stress concentrations, shall not exceed two times the stress values of Section II, Part D, Subpart 1, Table 4.

NB-3232.2 Maximum Stress.

The maximum value of service stress, except as restricted by NB-3232.3(b), at the periphery of the bolt cross section resulting from direct tension plus bending and neglecting stress concentrations shall not exceed three times the stress values of Section II, Part D, Subpart 1, Table 4. Stress intensity, rather than maximum stress, shall be limited to this value when the bolts are tightened by methods other than heaters, stretchers, or other means which minimize residual torsion.

NB-3232.3 Fatigue Analysis of Bolts.

Unless the components on which they are installed meet all the conditions of NB-3222.4(d) and thus require no fatigue analysis, the suitability of bolts for cyclic service shall be determined in accordance with the procedures of (a) through (e) below.

(a) *Bolting Having Less Than 100.0 ksi (689 MPa) Tensile Strength.* Bolts made of material which has specified minimum tensile strength of less than 100.0 ksi (689 MPa) shall be evaluated for cyclic service by the methods of NB-3222.4(e), using the applicable design fatigue curve of Figs. I-9.0 and an appropriate fatigue strength reduction factor [NB-3232.3(c)].

(b) *High Strength Alloy Steel Bolting.* High strength alloy steel bolts and studs may be evaluated for cyclic service by the methods of NB-3222.4(e) using the design fatigue curve of Fig. I-9.4 provided:

(1) the maximum value of the service stress (NB-3232.2) at the periphery of the bolt cross section, resulting from direct tension plus bending and neglecting stress concentration, shall not exceed $2.7S_m$ if the higher of the two fatigue design curves given in Fig. I-9.4 is used. The $2S_m$ limit for direct tension is unchanged.

(2) threads shall be of a Vee-type having a minimum thread root radius no smaller than 0.003 in. (0.076 mm);

(3) fillet radii at the end of the shank shall be such that the ratio of fillet radius to shank diameter is not less than 0.060.

(c) *Fatigue Strength Reduction Factor (NB-3213.17).* Unless it can be shown by analysis or tests that a lower value is appropriate, the fatigue strength reduction factor used in the fatigue evaluation of threaded members shall not be less than 4.0. However, when applying the rules of NB-3232.3(b) for high strength alloy steel bolts, the value used shall not be less than 4.0.

(d) *Effect of Elastic Modulus.* Multiply S_{alt} (as determined in NB-3216.1 or NB-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve at this value on the ordinate axis and find the corresponding number of cycles on the

abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(e) *Cumulative Damage*. The bolts shall be acceptable for the specified cyclic application of loads and thermal stresses provided the cumulative usage factor U , as determined in NB-3222.4(e)(5), does not exceed 1.0.

NB-3233 Level B Service Limits

Level A Service Limits (NB-3232) apply.

NB-3234 Level C Service Limits

The stress limits of NB-3232.1 and NB-3232.2 apply.

NB-3235 Level D Service Limits

If the Design Specifications specify any Service Loadings for which Level D Limits are designated

Page 92

[NCA-2142.4(b)(4)], the rules contained in Appendix F may be used in evaluating these loadings independently of all other Design and Service Loadings.

NB-3236 Design Stress Intensity Values

The design stress intensity values S_m are given in Section II, Part D, Subpart 1, Table 4 for bolting. Values for intermediate temperature may be found by interpolation. The basis for establishing stress intensity values is given in Appendix III.

NB-3300 VESSEL DESIGN

NB-3310 GENERAL REQUIREMENTS

NB-3311 Acceptability

The requirements for acceptability of a vessel design are as follows.

(a) The design shall be such that the requirements of NB-3100 and NB-3200 shall be satisfied.

(b) The rules of this Subarticle shall be met. In cases of conflict between NB-3200 and NB-3300 the requirements of NB-3300 shall govern.

NB-3320 DESIGN CONSIDERATIONS

NB-3321 Design and Service Loadings

The provisions of NB-3110 apply.

NB-3322 Special Considerations

The provisions of NB-3120 apply.

NB-3323 General Design Rules

The provisions of NB-3130 apply except when they conflict with rules of this Subarticle. In case of conflict, this Subarticle governs in the design of vessels.

NB-3324 Tentative Pressure Thickness

The following formulas are given as an aid to the designer for determining a tentative thickness for use in the design. They are not to be construed as formulas for acceptable thicknesses. However, except in local regions (NB-3221.2), the

wall thickness of a vessel shall never be less than that obtained from the formulas in NB-3324.1 and NB-3324.2, in which:

P	= Design Pressure, psi
R	= inside radius of shell or head, in.
R_o	= outside radius of shell or head, in.
S_m	= design stress intensity values (Section II, Part D, Subpart 1, Tables 2A and 2B), psi
t	= thickness of shell or head, in.

NB-3324.1 Cylindrical Shells

$$t = \frac{PR}{S_m - 0.5P} \quad \text{or} \quad t = \frac{PR_o}{S_m + 0.5P}$$

NB-3324.2 Spherical Shells

$$t = \frac{PR}{2S_m - P} \quad \text{or} \quad t = \frac{PR_o}{2S_m}$$

NB-3330 OPENINGS AND REINFORCEMENT

NB-3331 General Requirements for Openings

(a) For vessels or parts thereof which meet the requirements of NB-3222.4(d), analysis showing satisfaction of the requirements of NB-3221.1, NB-3221.2, NB-3221.3, and NB-3222.2 in the immediate vicinity of the openings is not required for pressure loading if the rules of NB-3330 are met.

(b) For vessels or parts thereof that do not meet the requirements of NB-3222.4(d) so that a fatigue analysis is required, the rules contained in NB-3330 ensure satisfaction of the requirements of NB-3221.1, NB-3221.2, and NB-3221.3 in the vicinity of openings, and no specific analysis showing satisfaction of those stress limits is required for pressure loading. The requirements of NB-3222.2 may also be considered to be satisfied if, in the vicinity of the nozzle, the stress intensity resulting from external nozzle loads and thermal effects, including gross but not local structural discontinuities, is shown by analysis to be less than $1.5S_m$. In this case, when evaluating the requirements of NB-3222.4(e), the peak stress intensity resulting from pressure loadings may be obtained by application of the stress index method of NB-3338 or NB-3339.

(c) The provisions of (a) and (b) above are not intended to restrict the design to any specified section thicknesses or other design details, provided the basic stress limits are satisfied. If it is shown by analysis that all the stress requirements have been met, the rules of NB-3330 are waived.

(d) Openings shall be circular, elliptical, or of any other shape which results from the intersection of a circular or elliptical cylinder with a vessel of the shapes permitted by this Subsection. Additional restrictions given in NB-3338.2(d) are applicable if the Stress Index

Page 93

Method is used. If fatigue analysis is not required, the restrictions on hole spacing are applicable unless there will be essentially no pipe reactions.

(e) Openings are not limited as to size except to the extent provided in NB-3338.2(d).

(f) All references to dimensions apply to the finished dimensions excluding material added as corrosion allowance. Rules regarding metal available for reinforcement are given in NB-3335.

(g) Any type of opening permitted in these rules may be located in a welded joint.

NB-3332 Reinforcement Requirements for Openings in Shells and Formed Heads

NB-3332.1 Openings Not Requiring Reinforcement.

The rules for openings not requiring reinforcement are given in (a) through (c) below, where R is the mean radius and t is the nominal thickness of the vessel shell or head at the location of the opening; and *locally stressed area* means any area in the shell where the primary local membrane stress exceeds $1.1S_m$ but excluding those areas where such primary local membrane stress is due to an unreinforced opening.

(a) A single opening has a diameter not exceeding $0.2\sqrt{Rt}$, or if there are two or more openings within any circle of diameter $2.5\sqrt{Rt}$, but the sum of the diameters of such unreinforced openings shall not exceed $0.25\sqrt{Rt}$.

(b) No two unreinforced openings shall have their centers closer to each other, measured on the inside of the vessel wall, than 1.5 times the sum of their diameters.

(c) No unreinforced opening shall have its center closer than $2.5\sqrt{Rt}$ to the edge of a locally stressed area in the shell.

NB-3332.2 Required Area of Reinforcement.

The total cross-sectional area of reinforcement A , required in any given plane for a vessel under internal pressure, shall not be less than:

$$A = dt_r F$$

where

d

= finished diameter of a circular opening or finished dimension (chord length) of an opening on the plane being considered for elliptical and obround openings in corroded condition, in.

F

= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of

a vessel. (A value of 1.00 shall be used for all configurations, except that Fig. NB-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.)

t_r

= the thickness which meets the requirements of NB-3221.1 in the absence of the opening, in.

FIG. NB-3332.2-1 CHART FOR DETERMINING
VALUE OF F

FIG. NB-3332.2-1 CHART FOR DETERMINING VALUE OF F

Not less than half the required material shall be on each side of the center line.

NB-3333 Reinforcement Required for Openings in Flat Heads

Flat heads that have an opening with a diameter that does not exceed one-half the head diameter shall have a total cross-sectional area of reinforcement not less than that given by the formula:

Page 94

$$A = 0.5dt_r$$

where d is as defined in NB-3332 and t_r is the thickness, in., which meets the requirements of NB-3221.1 and NB-3221.3 in the absence of the opening.

NB-3334 Limits of Reinforcement

The boundaries of the cross-sectional area in any plane normal to the vessel wall and passing through the center of the opening and within which metal shall be located in order to have value as reinforcement are designated as the limits of reinforcement for that plane and are given in the following subparagraphs.

NB-3334.1 Limit of Reinforcement Along the Vessel Wall.

The limits of reinforcement, measured along the midsurface of the nominal wall thickness, shall meet the following.

(a) One hundred percent of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) the diameter of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus the sum of the thicknesses of the vessel wall and the nozzle wall.

(b) Two-thirds of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) $r + 0.5\sqrt{Rt}$, where R is the mean radius of shell or head, t is the nominal vessel wall thickness, and r is the radius of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus two-thirds the sum of the thicknesses of the vessel wall and the nozzle wall.

NB-3334.2 Limit of Reinforcement Normal to the Vessel Wall.

The limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to the following limits as shown in Fig. NB-3338.2(a)-2.

(a) For Fig. NB-3338.2(a)-2 sketches (a), (b), (d), and (e):

$$\text{Limit} = 0.5\sqrt{r_i^2 - t_n^2} + 0.5r_2$$

where

r_i = inside radius, in.

r_m = mean radius, in.

$$= r_i + 0.5t_n$$

r_2 = transition radius, in., between nozzle and wall

t_n = nominal nozzle thickness, as indicated, in.

For the case of a nozzle with a tapered inside diameter, the limit shall be obtained by using r_i and t_n values at the nominal outside diameters of the vessel wall [Fig. NB-3338.2(a)-2 sketch (e)].

(b) For Fig. NB-3338.2(a)-2 sketches (c) and (f):

$$\text{Limit} = 0.5 \sqrt{r_m t_n}$$

where

r_i	= inside radius, in.
r_m	= $r_i + 0.5t_p$ in.
t_n	= $t_p + 0.667X$
t_p	= nominal thickness of the attached pipe, in.
X	= slope offset distance, in.
θ	= angle between vertical and slope, 45 deg. or less

For the case of a nozzle with a tapered inside diameter, the limit shall be obtained by using r_i and t_n values at the center of gravity of nozzle reinforcement area. These values must be determined by a trial and error procedure [Fig. NB-3338.2(a)-2 sketch (f)].

NB-3335 Metal Available for Reinforcement

Metal may be counted as contributing to the area of reinforcing called for in NB-3332, provided it lies within the limits of reinforcement specified in NB-3334, and shall be limited to material which meets the following requirements:

(a) metal forming a part of the vessel wall which is in excess of that required on the basis of membrane stress intensity (NB-3221.1) and is exclusive of corrosion allowance;

(b) similar excess metal in the nozzle wall, provided the nozzle is integral with the vessel wall or is joined to it by a full penetration weld;

(c) weld metal which is fully continuous with the vessel wall;

(d) the mean coefficient of thermal expansion of metal to be included as reinforcement under (b) and (c) above shall be within 15% of the value of the vessel wall material;

(e) metal not fully continuous with the shell, such as that in nozzles attached by partial penetration welds, shall not be counted as reinforcement;

(f) metal available for reinforcement shall not be considered as applying to more than one opening.

NB-3336 Strength of Reinforcing Material

Material used for reinforcement shall preferably be the same as that of the vessel wall. If the material of

Page 95

the nozzle wall or reinforcement has a lower design stress intensity value S_m than that for the vessel material, the amount of area provided by the nozzle wall or reinforcement in satisfying the requirements of NB-3332 shall be taken as the actual area provided multiplied by the ratio of the nozzle or reinforcement design stress intensity value to the vessel material design stress intensity value. No reduction in the reinforcing required may be taken for the increased strength of reinforcing material and weld metal having higher design stress intensity values than that of the material of the vessel wall. The strength of the material at the point under consideration shall be used in fatigue analyses.

NB-3337 Attachment of Nozzles and Other Connections

NB-3337.1

Nozzles and other Category D connections (NB-3351) shall be attached to the shell or head of the vessel by one of the methods provided in NB-3352.

NB-3337.2 Full Penetration Welded Nozzles.

Full penetration welds, as shown in Figs. NB-4244(a)-1, NB-4244(b)-1, NB-4244(c)-1, and NB-4244(e)-1 may be used (except as otherwise provided in NB-3337.3) for the purpose of achieving continuity of metal and facilitating the required radiographic examination. When all or part of the required reinforcement is attributable to the nozzle, the nozzle shall be attached by full penetration welds through either the vessel or the nozzle thickness, or both.

NB-3337.3 Partial Penetration Welded Nozzles

(a) Partial penetration welds, as shown in Figs. NB-4244(d)-1 and NB-4244(d)-2, are allowed only for nozzles on which there are substantially no piping reactions, such as control rod housings, pressurizer heater wells, and openings for instrumentation. Earthquake loadings need not be considered in determining whether piping reactions are substantial. For such nozzles, all reinforcement shall be integral with the portion of the vessel penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the nozzles. Nozzles attached by partial penetration welds shall have an interference fit or a maximum diametral clearance between the nozzle and the vessel penetration of:

- (1) 0.010 in. (0.25 mm) for $d \leq 1$ in. (25 mm)
- (2) 0.020 in. (0.51 mm) for 1 in. (25 mm) $< d \leq 4$ in. (102 mm)
- (3) 0.030 in. (0.76 mm) for $d > 4$ in. (102 mm)

where d is the outside diameter of the nozzle, except that the above limits on maximum clearance need not be met for the full length of the opening, provided there is a region at the weld preparation and a region near the end of the opening opposite the weld that does meet the above limits on maximum clearance and the latter region is extensive enough (not necessarily continuous) to provide a positive stop for nozzle deflection.

(b) In satisfying the limit of NB-3222.2, the stress intensities resulting from pressure induced strains (dilation of hole) may be treated as secondary in the penetrating part of partial penetration welded construction, provided the requirements of NB-3352.4(d) and Fig. NB-4244(d)-1 are fulfilled.

NB-3338 Fatigue Evaluation of Stresses in Openings

NB-3338.1 General.

For the purpose of determining peak stresses around the opening, three acceptable methods are listed below.

(a) *Analytical Method.* This method uses suitable analytical techniques such as finite element computer analyses, which provide detailed stress distributions around openings. In addition to peak stresses due to pressure, the effects of other loadings shall be included. The total peak stress at any given point shall be determined by combining stresses due to pressure, thermal, and external loadings in accordance with the rules of NB-3200.

(b) *Experimental Stress Analysis.* This is based on data from experiments (Appendix II).

(c) *Stress Index Method.* This uses various formulas together with available data obtained from an extensive series of tests covering a range of variation of applicable dimensional ratios and configurations (NB-3338.2). This method covers only single, isolated openings. Stress indices may also be determined by theoretical or experimental stress analysis.

NB-3338.2 Stress Index Method

(a) The term *stress index*, as used herein, is defined as the numerical ratio of the stress components σ_r , σ_θ , and σ_z [Fig. NB-3338.2(a)-1] under consideration to the computed membrane hoop stress in the unpenetrated vessel material; however, the material which increases the thickness of a vessel wall locally at the nozzle shall not be included in the calculations of these stress components. When the thickness of the vessel wall is increased over that required to the extent provided hereinafter, the values of r_1 and r_2 in Fig. NB-3338.2(a)-2 shall be referred to the thickened section.

FIG. NB-3338.2(a)-1 DIRECTION OF STRESS COMPONENTS

FIG. NB-3338.2(a)-1 DIRECTION OF STRESS COMPONENTS

(b) The nomenclature used in NB-3338 is defined as follows.

R	= inside radius, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.
S	= stress intensity (combined stress) at the point under consideration, psi
t	= nominal wall thickness, less corrosion allowance, of vessel or head, in.
σ_n	= stress component normal to the plane of the section (ordinarily the circumferential stress around the hole in the

shell), psi

σ_r = stress component normal to the boundary of the section, psi
 σ_t = stress component in the plane of the section under consideration and parallel to the boundary of the section, psi

(c) When the conditions of (d) below are satisfied, the stress indices of Table NB-3338.2(c)-1 may be used for nozzles designed in accordance with the applicable rules of NB-3330. These stress indices deal only with the maximum stresses, at certain general locations, due to internal pressure. In the evaluation of stresses in or adjacent to vessel openings and connections, it is often necessary to consider the effect of stresses due to external loadings or thermal stresses. In such cases, the total stress at a given point may be determined by superposition. In the case of combined stresses due to internal pressure and nozzle loading, the maximum stresses for a given location shall be considered as acting at the same point and added algebraically unless positive evidence is available to the contrary.

(d) The indices of Table NB-3338.2(c)-1 apply when the conditions stipulated in (1) through (7) below exist.

(1) The opening is for a circular nozzle whose axis is normal to the vessel wall. If the axis of the nozzle makes an angle ϕ with the normal to the vessel wall and if $d/D \leq 0.15$, an estimate of the σ_n index on the inside may be obtained from one of the following formulas.

For hillside connections in spheres or cylinders:

$$K_2 = K_1 (1 + 2 \sin^2 \phi)$$

For lateral connections in cylinders:

$$K_2 = K_1 [1 + (\tan \phi)^{4/3}]$$

where

K_1 = the σ_n inside stress index of Table NB-3338.2(c)-1 for a radial connection
 K_2 = the estimated σ_n inside stress index for the nonradial connection

(2) The arc distance measured between the center lines of adjacent nozzles along the inside surface of the shell is not less than three times the sum of their inside radii for openings in a head or along the longitudinal axis of a shell and is not less than two times the sum of their radii for openings along the circumference of a cylindrical shell. When two nozzles in a cylindrical shell are neither in a longitudinal line nor in a circumferential arc, their center line distance along the inside surface of the shell shall be such that $[(L_c/2)^2 + (L_l/3)^2]^{1/2}$ is not less than the sum of their inside radii, where L_c is the component of the center line distance in the circumferential direction and L_l is the component of the center line distance in the longitudinal direction.

(3) The following dimensional ratios are met:

Ratio	Cylinder	Sphere
D/t	10 to 100	10 to 100
d/D	0.5 max.	0.5 max.
$d/\sqrt{Dt}$	...	0.8 max.
$d/\sqrt{Dt} \sqrt{t_2/t}$	1.5 max.	...

where D is the inside shell diameter, t is the shell thickness, and d is the inside nozzle diameter. In the case of cylindrical shells, the total nozzle reinforcement area on the transverse axis of the connections, including any outside of the reinforcement limits, shall not exceed 200% of that required for the longitudinal axis (compared to 50% permitted by Fig. NB-3332.2-1) unless a tapered transition section is incorporated into the

reinforcement and the shell, meeting the requirements of NB-3361.

FIG. NB-3338.2(a)-2 NOZZLE DIMENSIONS

FIG. NB-3338.2(a)-2 NOZZLE DIMENSIONS

**TABLE NB-3338.2(c)-1
STRESS INDICES FOR NOZZLES**

Nozzles in Spherical Shells and Formed Heads		
Stress	Inside Corner	Outside Corner
σ_n	2.0	2.0
σ_t	- 0.2	2.0
σ_r	- 2t/R	0
S	2.2	2.0

Nozzles in Cylindrical Shells				
Stress	Longitudinal Plane		Transverse Plane	
	Inside	Outside	Inside	Outside
σ_n	3.1	1.2	1.0	2.1
σ_t	- 0.2	1.0	- 0.2	2.6
σ_r	- t/R	0	- t/R	0
S	3.3	1.2	1.2	2.6

TABLE NB-3338.2(c)-1 STRESS INDICES FOR NOZZLES

(4) In the case of spherical shells and formed heads, at least 40% of the total nozzle reinforcement area shall be located beyond the outside surface of the minimum required vessel wall thickness.

(5) The inside corner radius r_1 [Fig. NB-3338.2(a)-2] is between 10% and 100% of the shell thickness t .

(6) The outer corner radius r_2 [Fig. NB-3338.2(a)-2] is large enough to provide a smooth transition between the nozzles and the shell. In addition, for opening diameters greater than $1\frac{1}{2}$ times the shell thickness in cylindrical shells and 2:1 ellipsoidal heads and greater than three shell thicknesses in spherical shells, the value of r_2 shall be not less than one-half the thickness of the shell or nozzle wall, whichever is greater.

(7) The radius r_3 [Fig. NB-3338.2(a)-2] is not less than the greater of the following:

(a) $0.002\theta d_o$, where d_o is the outside diameter of the nozzle and is as shown in Fig. NB-3338.2(a)-2, and the angle θ is expressed in degrees;

(b) $2(\sin \theta)^3$ times offset for the configuration shown in Fig. NB-3338.2(a)-2 sketches (a) and (b).

NB-3339

Subject to the limitations stipulated in NB-3339.1, the requirements of this paragraph constitute an acceptable alternative to the rules of NB-3332 through NB-3336 and NB-3338.

NB-3339.1 Limitations.

These alternative rules are applicable only to nozzles in vessels within the limitations stipulated in (a) through (f) below.

(a) The nozzle is circular in cross section and its axis is normal to the vessel or head surface.

(b) The nozzle and reinforcing (if required) are welded integrally into the vessel with full penetration welds. Details such as those shown in Figs. NB-4244(a)-1, NB-4244(b)-1, and NB-4244(c)-1 are acceptable. However, fillet welds shall be finished to a radius in accordance with Fig. NB-3339.1(b)-1.

(c) In the case of spherical shells and formed heads, at least 40% of the total nozzle reinforcement area shall be located beyond the outside surface of the minimum required vessel wall thickness.

(d) The spacing between the edge of the opening and the nearest edge of any other opening is not less than the smaller of $1.25(d_1 + d_2)$ or $2.5\sqrt{Rt}$, but in any case not less than $d_1 + d_2$, where d_1 and d_2 are the inside diameters of the openings.

(e) The material used in the nozzle, reinforcing, and vessel adjacent to the nozzle shall have a ratio of UTS/YS of not less than 1.5, where

UTS = specified minimum ultimate tensile strength, ksi

YS = specified minimum yield strength, ksi

(f) The following dimensional limitations are met:

	Nozzles in Cylindrical Vessels	Nozzles in Spherical Vessels or Hemispherical Heads
D/t	10 to 100	10 to 100
d/D	0.5 max.	0.5 max.
$d/\sqrt{Dt}$	...	0.8 max.
$d/\sqrt{Dt_n} \sqrt{t}$	1.5 max.	...

NB-3339.2 Nomenclature.

The nomenclature used in NB-3339 is defined as follows:

A_a	= available reinforcing area, sq in.
A_r	= required minimum reinforcing area, sq in.
D	= inside diameter, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.
d	= inside diameter, in corroded condition, of the nozzle, in.
R	= inside radius, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.
t	= nominal wall thickness, less corrosion allowance, of vessel or head, in.
t_n	= nominal wall thickness, less corrosion allowance, of nozzle, in.

t_r

= wall thickness of vessel or head, computed by the equations given in NB-3324.1 for cylindrical vessels and in NB-3324.2 for spherical vessels or spherical heads, in.

t_m

= wall thickness of nozzle, computed by the equation given in NB-3324.1, in.

FIG. NB-3339.1(b)-1 EXAMPLES OF ACCEPTABLE TRANSITION DETAILS

FIG. NB-3339.1(b)-1 EXAMPLES OF ACCEPTABLE TRANSITION DETAILS

For the definitions of $r_1, r_2, r_3, r_4, \theta$, and θ_1 see Fig. NB-3339.1(b)-1; for L_c and L_n see Fig. NB-3339.4-1; for S, σ_p, σ_n , and σ_r see NB-3338.2 and Fig. NB-3338.2(a)-1.

NB-3339.3 Required Reinforcement Area.

The required minimum reinforcing area is related to the value of $d/\sqrt{Rt_r}$ as tabulated in Table NB-3339.3-1. The required minimum reinforcing area shall be provided in all planes containing the nozzle axis.

NB-3339.4 Limits of Reinforcing Zone.

Reinforcing metal included in meeting the minimum required reinforcing area specified in Table NB-3339.3-1 must be located within the reinforcing zone boundary shown in Fig. NB-3339.4-1.

NB-3339.5 Strength of Reinforcing Material Requirements.

Material in the nozzle wall used for reinforcing shall preferably be the same as that of the vessel wall. If material with a

lower design stress intensity value S_m is used, the area provided by such material shall be increased in proportion to the inverse ratio of the stress values of the nozzle and the vessel wall material. No reduction in the reinforcing area requirement shall be taken for the increased strength of nozzle material or weld metal which has a higher

design stress intensity value than that of the material of the vessel wall. The strength of the material at the point under consideration shall be used in fatigue analyses. The mean coefficient of thermal expansion of metal to be included as reinforcement shall be within 15% of the value for the metal of the vessel wall.

TABLE NB-3339.3-1 REQUIRED MINIMUM REINFORCING AREA, A_r .

FIG. NB-3339.4-1 LIMITS OF REINFORCING ZONE

FIG. NB-3339.4-1 LIMITS OF REINFORCING ZONE

NB-3339.6 Transition Details.

Examples of acceptable transition tapers and radii are shown in Fig. NB-3339.1(b)-1. Other configurations which meet the reinforcing area requirements of NB-3339.3 and with equivalent or less severe transitions are also acceptable; e.g., larger radius-thickness ratios.

NB-3339.7 Stress Indices

(a) The term *stress index*, as used herein, is defined as the numerical ratio of the stress components σ_r , σ_n , and σ_t , under consideration, to the computed stress σ .

(b) The nomenclature for the stress components is shown in Fig. NB-3338.2(a)-1 and is defined as follows:

P	= service pressure, psi
S	= stress intensity (combined stress) at the point under consideration, psi
σ	= $P(D + t)/4t$ for nozzles in spherical vessels or heads, psi = $P(D + t)/2t$ for nozzles in cylindrical vessels, psi
σ_n	= stress component normal to the plane of the section (ordinarily the circumferential stress around the hole in the shell), psi

Page 101

σ_r	= stress component normal to the boundary of the section, psi
σ_t	= stress component in the plane of the section under consideration and parallel to the boundary of the section, psi

**TABLE NB-3339.7(c)-1
STRESS INDICES FOR INTERNAL
PRESSURE LOADING**

Nozzles in Spherical Shells and Spherical Heads		
Stress	Inside	Outside
σ_n	$2.0 - d/D$	$2.0 - d/D$
σ_t	-0.2	$2.0 - d/D$
σ_r	$-4t/(D + t)$	0
S	larger of: $2.2 - d/D$ or $2.0 + [4t/(D + t)] - d/D$	$2.0 - d/D$

Nozzles in Cylindrical Shells				
Stress	Longitudinal Plane		Transverse Plane	
	Inside	Outside	Inside	Outside
σ_n	3.1	1.2	1.0	2.1
σ_t	-0.2	1.0	-0.2	2.6
σ_r	$-2t/(D + t)$	0	$-2t/(D + t)$	0
S	3.3	1.2	1.2	2.6

TABLE NB-3339.7(c)-1 STRESS INDICES FOR INTERNAL PRESSURE LOADING

(c) When the conditions of NB-3339.1 through NB-3339.6 are satisfied, the stress indices given in Table NB-3339.7(c)-1 may be used. These stress indices deal only with the maximum stresses, at certain general locations, due to internal pressure. In the evaluation of stresses in or adjacent to vessel openings and connections, it is often necessary to consider the effect of stresses due to external loadings or thermal stresses. In such cases, the total stress at a given point may be determined by superposition. In the case of combined stresses due to internal pressure and nozzle loading, the maximum stresses shall be considered as acting at the same point and added algebraically. If the stresses are otherwise determined by more accurate analytical techniques or by the experimental stress analysis procedure of Appendix II, the stresses are also to be added algebraically.

NB-3340 ANALYSIS OF VESSELS

The provisions of NB-3214 apply.

NB-3350 DESIGN OF WELDED CONSTRUCTION

NB-3351 Welded Joint Category

The term *Category* defines the location of a joint in a vessel, but not the type of joint. The categories established are for use in specifying special requirements regarding joint type and degree of examination for certain welded joints. Since these special requirements, which are based on service, material, and thickness, do not apply to every welded joint, only those joints to which special requirements apply are included in the categories. The special requirements apply to joints of a given category only when specifically stated. The joints included in each category are designated as joints of Categories A, B, C, and D. Figure NB-3351-1 illustrates typical joint locations included in each category.

NB-3351.1 Category A.

Category A comprises longitudinal welded joints within the main shell, communicating chambers,¹³ transitions in diameter, or nozzles; any welded joint within a sphere, within a formed or flat head, or within the side plates¹⁴ of a flat sided vessel; and circumferential welded joints connecting hemispherical heads to main shells, to transitions in diameters, to nozzles, or to communicating chambers.

NB-3351.2 Category B.

Category B comprises circumferential welded joints within the main shell, communicating chambers, nozzles, or transitions in diameter, including joints between the transition and a cylinder at either the large or small end; and circumferential welded joints connecting formed heads other than hemispherical to main shells, to transitions in diameter, to nozzles, or to communicating chambers.

NB-3351.3 Category C.

Category C comprises welded joints connecting flanges, Van Stone laps, tubesheets, or flat heads to main shell, to formed heads, to transitions in diameter, to nozzles, or to communicating chambers¹³ any welded joint connecting one side plate¹⁴ to another side plate of a flat sided vessel.

¹³ Communicating chambers are defined as portions of the vessel which intersect the shell or heads of a vessel and form an integral part of the pressure-retaining closure, e.g., sumps.

¹⁴ Side plates of a flat sided vessel are defined as any of the flat plates forming an integral part of the pressure-retaining enclosure.

FIG. NB-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

FIG. NB-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

NB-3351.4 Category D.

Category D comprises welded joints connecting communicating chambers or nozzles to main shells, to spheres, to transitions in diameter, to heads, or to flat sided vessels, and those joints connecting nozzles to communicating chambers. For nozzles at the small end of a transition in diameter, see Category B.

NB-3352 Permissible Types of Welded Joints

The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle α not exceeding 30 deg. are considered as meeting the requirements for butt joints. Figure NB-3352-1 shows typical butt welds for each category joint.

NB-3352.1 Joints of Category A.

All welded joints of Category A as defined in NB-3351 shall meet the fabrication requirements of NB-4241 and shall be capable of being examined in accordance with NB-5210.

NB-3352.2 Joints of Category B.

All welded joints of Category B as defined in NB-3351 shall meet the fabrication requirements of NB-4242 and shall be capable of being examined in accordance with NB-5220. When joints with opposing lips to form an integral backing strip or joints with backing strips not later removed are used, the suitability for cyclic service shall be analyzed by the method of NB-3222.4 using a fatigue strength reduction factor of not less than 2.

NB-3352.3 Joints of Category C.

All welded joints of Category C as defined in NB-3351 shall meet the fabrication requirements of NB-4243 and shall be capable of being examined in accordance with NB-5230. Minimum dimensions of the welds and throat thickness shall be as shown in Fig. NB-4243-1 where:

(a) for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle not greater than 45 deg. measured from the face:

t

t, t_n	= nominal thicknesses of welded parts, in.
t_c	= $0.7t_n$ or $1/4$ in. (6 mm), whichever is less
t_w	= $t_n/2$ or $t/4$, whichever is less

(b) for all other material forms and for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle greater than 45 deg. measured from the face:

t, t_n	= nominal thicknesses of welded parts, in.
t_c	= $0.7t_n$ or $1/4$ in. (6 mm), whichever is less
t_w	= t_n or $t/2$, whichever is less

NB-3352.4 Joints of Category D.

All welded joints of Category D as defined in NB-3351 shall be in accordance with the requirements of one of (a) through (e) below.

(a) *Butt Welded Nozzles*. Nozzles shall meet the fabrication requirements of NB-4244(a) and shall be capable of being examined in accordance with NB-5242. The minimum dimensions and geometrical requirements of Fig. NB-4244(a)-1 shall be met, where

r_1	= $1/4t$ or $3/4$ in. (19 mm), whichever is less
r_2	= $1/4$ in. (6 mm) minimum
t	= nominal thickness of part penetrated, in.

t_n	= nominal thickness of penetrating part, in.
-------	--

FIG. NB-3352-1 TYPICAL BUTT JOINTS

FIG. NB-3352-1 TYPICAL BUTT JOINTS

(b) *Full Penetration Corner Welded Nozzles.* Nozzles shall meet the fabrication requirements of NB-4244(b) and shall be capable of being examined as required in NB-5243. The minimum dimensions of Fig. NB-4244(b)-1 shall be met, where

r_1	$= \frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	$= \frac{1}{4}$ in. (6 mm) minimum
t	$=$ nominal thickness of part penetrated, in.
t_c	$= 0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
t_n	$=$ nominal thickness of penetrating part, in.

(c) *Use of Deposited Weld Metal for Openings and Nozzles*

(1) Nozzles shall meet the fabrication requirements of NB-4244(c) and shall be capable of being examined in accordance with NB-5244.

(2) When the deposited weld metal is used as reinforcement, the coefficients of thermal expansion of the base metal, the weld metal, and the nozzle shall not differ by more than 15% of the lowest coefficient involved.

(3) The minimum dimensions of Fig. NB-4244(c)-1 shall be met, where

r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
t	= nominal thickness of part penetrated, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
t_n	= nominal thickness of penetrating part, in.

(4) The corners of the end of each nozzle neck extending less than $\sqrt{d}t_n$ beyond the inner surface of the part penetrated shall be rounded to a radius of one-half the thickness t_n of the nozzle neck or $\frac{3}{4}$ in. (19 mm), whichever is smaller.

(d) Attachment of Nozzles Using Partial Penetration Welds

(1) Partial penetration welds used to connect nozzles as permitted in NB-3337.3 shall meet the fabrication

Page 104

requirements of NB-4244(d) and shall be capable of being examined in accordance with the requirements of NB-5245.

(2) The minimum dimensions of Figs. NB-4244(d)-1 and NB-4244(d)-2 shall be met, where

d	= outside diameter of nozzle or of the inner cylinder as shown in Fig. NB-4244(d)-2
r_1	= $\frac{1}{4}t_n$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{16}$ in. (1.6 mm) minimum
r_3	= r_2 or equivalent chamfer minimum
r_4	= $\frac{1}{2}t_n$ or $\frac{3}{4}$ in. (19 mm), whichever is less
t	= nominal thickness of part penetrated, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
t_n	= nominal thickness of penetrating part or the lesser of t_{n1} or t_{n2} in Fig. NB-4244(d)-2, in.
λ	= $\frac{1}{16}$ in. (1.6 mm) minimum
λ	= t_n maximum, in.

(3) The corners of the end of each nozzle, extending less than $\sqrt{d}t_n$ beyond the inner surface of the part penetrated, shall be rounded to a radius of one-half of the thickness t_n of the penetrating part or $\frac{3}{4}$ in. (19 mm), whichever is smaller.

(4) Weld groove design for partial penetration joints attaching nozzles may require special consideration to achieve the $1.25t_n$ minimum depth of weld and adequate access for welding examination. The welds shown in the sketches of Figs. NB-4244(d)-1 and NB-4244(d)-2 may be on either the inside or the outside of the vessel shell. Weld preparation may be J-groove as shown in the figures or straight bevel.

(5) A fatigue strength reduction factor of not less than four shall be used when fatigue analysis is required.

(e) Oblique Full Penetration Nozzles. Internal or external nozzles shall meet the fabrication requirements of NB-4244 (e) and shall be capable of being examined in accordance with NB-5246. Radiography of the nozzle weld may be waived by NB-5246, provided the requirements of (1) through (6) below are met.

(1) The inside nozzle diameter shall not exceed 6 in.

(2) The angle which the nozzle axis makes with the vessel wall at the point of attachment shall not be smaller than 40 deg.

(3) The opening shall be completely reinforced, with the reinforcement located in the shell or head of the vessel.

(4) The nozzle shall be subjected to essentially no pipe reactions and no thermal stresses greater than in the vessel itself.

(5) The nozzle wall and the weld shall develop the full strength of the nozzle.

(6) The minimum dimensions of Fig. NB-4244(e)-1 shall be met, where

r_1	= $\frac{1}{2}$ or $\frac{3}{4}$ in. (19 mm), whichever is less
t	= nominal thickness of part penetrated, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
t_n	= nominal thickness of penetrating part, in.

NB-3354 Structural Attachment Welds

Welds for structural attachments shall meet the requirements of NB-4430.

NB-3355 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and complete joint penetration, except as otherwise permitted in NB-3352.4.

NB-3357 Thermal Treatment

All vessels and vessel parts shall be given the appropriate postweld heat treatment prescribed in NB-4620.

NB-3360 SPECIAL VESSEL REQUIREMENTS

NB-3361 Category A or B Joints Between Sections of Unequal Thickness

In general, a tapered transition section as shown in Fig. NB-3361-1 which is a type of gross structural discontinuity (NB-3213.2) shall be provided at joints of Categories A and B between sections that differ in thickness by more than one-fourth the thickness of the thinner section. The transition section may be formed by any process that will provide a uniform taper. An ellipsoidal or hemispherical head which has a greater thickness than a cylinder of the same inside diameter may be machined to the outside diameter of the cylinder provided the remaining thickness is at least as great as that required for a shell of the same diameter. A uniform taper is not required for flanged hubs. The adequacy of the transition shall be evaluated by stress analysis. Stress intensity limitations are given in NB-3220. The requirements of this paragraph do not apply to flange hubs.

NB-3362 Bolted Flange Connections

It is recommended that the dimensional requirements of bolted flange connections to external piping conform to ANSI B16.5, Steel Pipe Flanges and Flanged Fittings.

GENERAL NOTE:

Length of taper may include the width of the weld.

**FIG. NB-3361-1 CATEGORY A AND B JOINTS
BETWEEN SECTIONS OF UNEQUAL THICKNESS**

FIG. NB-3361-1 CATEGORY A AND B JOINTS BETWEEN SECTIONS OF UNEQUAL THICKNESS

NB-3363 Access Openings

Access openings, where provided, shall consist of handhole or manhole openings having removable covers. These may be located on either the inside or outside of the shell or head openings and may be attached by studs or bolts in combination with gaskets or welded membrane seals or strength welds. Plugs using pipe threads are not permitted.

NB-3364 Attachments

Attachments used to transmit support loads shall meet the requirements of NB-3135.

NB-3365 Supports

All vessels shall be so supported and the supporting members shall be arranged and attached to the vessel wall in such a way as to provide for the maximum imposed loadings. The stresses produced in the vessel by such loadings and by steady state and transient thermal conditions shall be subjected to the stress limits of this Subsection. Additional requirements are given in NCA-3240 and Subsection NF.

NB-3400 PUMP DESIGN

NB-3410 GENERAL REQUIREMENTS FOR CENTRIFUGAL PUMPS

NB-3411 Scope

NB-3411.1 Applicability.

The rules of NB-3400 apply to (a) through (j) below.

(a) pump casings

(b) pump inlets and outlets

(c) pump covers

(d) clamping rings

(e) seal housing and seal glands

(f) related bolting

(g) pump internal heat exchanger piping

(h) pump auxiliary nozzle connections up to the face of the first flange or circumferential joint in welded connections, excluding the connecting weld

(i) piping identified with the pump and external to and forming part of the pressure-retaining boundary and supplied with the pump

(j) mounting feet or pedestal supports when integrally attached to the pump pressure-retaining boundary and supplied with the pump

[98]

NB-3411.2Exemptions.

The rules of NB-3400 do not apply to (a) through (c) below.

(a) pump shafts and impellers; shafts may be designed in accordance with Appendix S

(b) nonstructural internals

(c) seal packages

[98]

NB-3412 Acceptability

[98]

NB-3412.1 Acceptability of Large Pumps.

The requirements for the design acceptability of pumps having an inlet connection greater than 4 in. nominal pipe size (DN 100) diameter are given in (a), (b), and (c) below.

(a) The design shall be such that the requirements of NB-3100 and of NB-3200 or Appendix II (provided the requirements of NB-3414 and the minimum wall thicknesses of NB-3430 are met) are satisfied.

(b) The rules of this Subarticle shall be met. In cases of conflict between NB-3100 and NB-3200 or Appendix II and NB-3400, the requirements of NB-3400 apply.

(c) The requirements for prevention of nonductile fracture as set forth in NB-3211(d) shall be met.

[98]

NB-3412.2 Acceptability of Small Pumps.

The requirements for the design acceptability of pumps having an inlet connection 4 in. nominal pipe size (DN 100) diameter or smaller are given in (a) and (b) below.

Page 106

(a) The design shall be such that the requirements of NB-3100 or Appendix II are satisfied.

(b) The rules of this Subarticle shall be met. In cases of conflict between NB-3100 or Appendix II and NB-3400, the requirements of this Subarticle shall apply.

NB-3414 Design and Service Conditions

The general design considerations, including definitions of NB-3100 plus the requirements of NB-3320, NB-3330, NB-3361, and NB-3362 are applicable to pumps.

NB-3415 Loads From Connected Piping

(a) Loads imposed on pump inlets and outlets by connected piping shall be considered in the pump casing design. The forces and moments produced by the connected piping on each pump inlet and outlet shall be provided by the Owner in the Design Specifications.

(b) Stresses generated in the pump casing by the connected piping shall be combined with the pressure stresses in accordance with the requirements of NB-3200.

NB-3417 Earthquake Loadings

(a) The effects of earthquake shall be considered in the design of pumps, pump supports, and restraints. The stresses resulting from these earthquake effects shall be included with the stresses resulting from pressure or other applied loads.

(b) Where pumps are provided with drivers on extended supporting structures and these structures are essential to maintaining pressure integrity, an analysis shall be performed when required by the Design Specifications.

NB-3418 Corrosion

The requirements of NB-3121 apply.

NB-3419 Cladding

Cladding dimensions used in the design of pumps shall be required as in NB-3122.

NB-3420 DEFINITIONS

NB-3421 Radially Split Casing

A radially split casing shall be interpreted as one in which the primary sealing joint is radially disposed around the shaft.

NB-3422 Axially Split Casing

An axially split casing shall be interpreted as one in which the primary sealing joint is axially disposed with respect to the shaft.

NB-3423 Single and Double Volute Casings

Figures NB-3423-1 and NB-3423-2 show typical single and double volute casings, respectively.

NB-3424 Seal Housing

Seal housing is defined as that portion of the pump cover or casing assembly which contains the seal and forms a part of the primary pressure boundary.

NB-3425 Typical Examples of Pump Types

Figures NB-3441.1-1 through NB-3441.6(a)-1 are typical examples to aid in the determination of pump type and are not to be considered as limiting. Bearing locations and inlet and outlet orientations are optional.

NB-3430 DESIGN REQUIREMENTS FOR CENTRIFUGAL PUMPS

NB-3431 Design of Welding

(a) The design of welded construction shall be in accordance with NB-3350.

(b) Partial penetration welds are permitted for piping connections 2 in. nominal pipe size and less when the requirements of NB-3337.3 and NB-3352.4(d) are met.

NB-3432 Cutwater Tip Stresses

(a) It is recognized that localized high stresses may occur at the cutwater tips of volute casings (Fig. NB-3441.3-2). Adequacy of the design in this area shall be demonstrated either by an investigation through experimental stress analysis in accordance with Appendix II

Page 107

or by detailing satisfactory service performance of other pumps under similar operating conditions.

FIG. NB-3423-1
TYPICAL SINGLE VOLUTE CASING

FIG. NB-3423-1 TYPICAL SINGLE VOLUTE CASING

**FIG. NB-3423-2
TYPICAL DOUBLE VOLUTE CASING**

FIG. NB-3423-2 TYPICAL DOUBLE VOLUTE CASING

(b) Where experimental stress analysis is used, stress intensity at this point shall meet the requirements of NB-3222.

NB-3433 Reinforcement of Pump Casing Inlets and Outlets

NB-3433.1 Axially Oriented Inlets and Outlets

(a) An axially oriented pump casing inlet or outlet shall be considered similar to an opening in a vessel and shall be reinforced. It shall be treated as required in NB-3331 through NB-3336.

(b) To avoid stress concentrations, the outside radius r_2 in Fig. NB-3441.3-2 shall not be less than one-half the thickness of the inlets and outlets as reinforced.

NB-3433.2 Radially Oriented Inlets and Outlets.

Reinforcement of radially oriented inlets and outlets in accordance with the rules of NB-3331 through NB-3336 is required.

NB-3433.3 Tangential Inlets and Outlets.

Except as modified in NB-3433.4, any design which has been demonstrated to be satisfactory for the specified Design Loadings may be used.

NB-3433.4 Minimum Inlet and Outlet Wall Thicknesses.

The wall thickness of the inlet or outlet shall not be less than the minimum wall thickness of the casing for a distance l as shown in Fig. NB-3433.4-1. The wall thickness beyond the distance l may be reduced to the minimum wall thickness of the connected piping. The change in wall thickness shall be gradual and have a maximum slope as indicated in Fig. NB-4250-1. The distance l in Fig. NB-3433.4-1 is the limit of reinforcement. The value of l , in., shall be determined from the relationship:

$$l = 0.5 \sqrt{r_i t_m}$$

where

r_i	= inlet or outlet inside radius, in. = $d_i/2$
r_m	= $r_i + 0.5t_m$, in.
t_m	= mean inlet or outlet wall thickness, in., taken between section x-x and a parallel section y-y

NB-3434 Bolting

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with NB-3230.

NB-3435 Piping

NB-3435.1 Piping Under External Pressure.

Piping located within the pressure-retaining boundary of the pump shall be designed in accordance with NB-3133.

NB-3435.2 Piping Under Internal Pressure.

Piping identified with the pump and external to or forming a part of the pressure-retaining boundary, such as auxiliary water connections, shall be designed in accordance with NB-3600.

FIG. NB-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESS

FIG. NB-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESS

NB-3436 Attachments

(a) External and internal attachments to pumps shall be designed so as not to cause excessive localized bending stresses or harmful thermal gradients in the pump as determined by the rules of NB-3200. Such attachments shall be designed to minimize stress concentrations in applications where the number of stress cycles, due either to pressure or thermal effect, is relatively large for the expected life of the equipment.

(b) Attachments shall meet the requirements of NB-3135.

NB-3437

Pump covers shall be designed in accordance with NB-3200.

NB-3438 Supports

Pump supports shall be designed in accordance with the requirements of Subsection NF unless included under the rules of NB-3411.1(j).

NB-3440 DESIGN OF SPECIFIC PUMP TYPES

NB-3441 Standard Pump Types

NB-3441.1 Design of Type A Pumps.

Type A pumps are those having single volutes and radially split casings with single suction, as illustrated in Figs. NB-3441.1-1 and NB-3441.1-2. Their design shall be in accordance with the requirements of this Subarticle.

NB-3441.2 Design of Type B Pumps.

Type B pumps are those having single volutes and radially split casings with double suction, as illustrated in Fig. NB-3441.2-1. Their design shall be in accordance with the requirements of this Subarticle.

NB-3441.3 Design of Type C Pumps.

Type C pumps are those having double volutes and radially split casings with single suction, as illustrated in Figs. NB-3441.3-1 and NB-3441.3-2. The splitter is considered a structural part of the casing. Casing design shall be in accordance with the requirements of this Subarticle and with those given in (a) through (d) below.

(a) *Casing Wall Thickness.* Except where specifically indicated in these rules, no portion of the casing wall shall be thinner than the value of t determined as follows:

$$t = (0.63 \times P \times A) / S_m$$

where

A	= scroll dimension inside casing as shown in Fig. NB-3441.3-2, in.
P	= Design Pressure, psig
S_m	= allowable stress intensity for casing material at Design Temperature, psi
t	= minimum allowable wall thickness, in.

(b) Splitter Wall Thickness

(1) The splitter shall have a minimum wall thickness of t as determined above for the casing wall and shall extend from point B in Fig. 3441.3-2 through a minimum angle of 135 deg. to point C. Beyond point C, the splitter wall may be reduced in thickness and tapered to blend with the cutwater tip radius.

(2) Cutwater tip and splitter tip radii shall not be less than $0.05t$.

(3) All cutwater and splitter fillets, including the tips, where they meet the casing wall, shall have a minimum radius of $0.10t$ or 0.25 in. (6 mm), whichever is greater.

(c) *Crotch Radius (Fig. NB-3441.3-2).* The crotch radius shall not be less than $0.3t$.

(d) Bottom of Casing

(1) That section of the pump casing within the diameter defined by dimension A in Fig. NB-3441.3-2 on the inlet side of the casing, normally referred to as the bottom of the casing (Fig. NB-3441.3-1), shall have a wall thickness no less than the value of t determined in (a) above.

(2) The casing surface shall be analyzed in accordance with an acceptable procedure, such as that shown for flat heads in A-5000, or by an experimental stress technique, such as described in Appendix II.

(3) The minimum permissible thickness of the bottom of the casing shall be the lesser of the value determined by the analysis in (2) above and the value obtained from the calculation shown in (a) above.

NB-3441.4 Design of Type D Pumps

(a) Type D pumps are those having double volutes and radially split casings with double suction as illustrated in Fig. NB-3441.4(a)-1. The design shall be in accordance with this Subarticle.

(b) The requirements of NB-3441.3(a), (b), and (c), governing casing wall thickness, splitter wall thickness, and crotch radius, apply.

(c) In the casing portion between the cover and the casing wall, a wall thickness in excess of t may be required.

NB-3441.5 Design of Type E Pumps.

Type E pumps are those having volute type radially split casings and multivane diffusers which form structural parts of the casing as illustrated in Fig. NB-3441.5-1. The design shall be in accordance with this Subarticle.

NB-3441.6 Design of Type F Pumps

(a) Type F pumps are those having radially split, axisymmetric casings with either tangential or radial outlets as illustrated in Fig. NB-3441.6(a)-1. The basic configuration of a Type F pump casing is a shell with a dished head attached at one end and a bolting flange at the other. The inlet enters through the dished head, and the outlet may be either tangent to the side or normal to the center line of the casing. Variations of these inlet and outlet locations are permitted.

(b) The design of Type F pumps shall be in accordance with this Subarticle.

NB-3442 Special Pump Types - Type J Pumps

(a) Type J pumps are those that cannot logically be classified with any of the preceding types.

(b) Any design method which has been demonstrated to be satisfactory for the specified Design Conditions may be used.

NB-3500 VALVE DESIGN

NB-3510 ACCEPTABILITY¹⁵

¹⁵ These requirements for the acceptability of a valve design are not intended to ensure the functional adequacy of the valve. However, for pressure relief valves the Designer is cautioned that the requirements of NB-7000 relative to set pressure, lift, blowdown, and closure shall be met.

¹⁶

CAUTIONARY NOTE: Certain types of double seated valves have the capability of trapping liquid in the body or bonnet cavity in the closed position. If such a cavity accumulates liquid and is in the closed position at a time when adjacent system piping is increasing in temperature, a substantial and uncontrolled increase in pressure in the body or bonnet cavity may result. Where such a condition is possible, it is the responsibility of the Owner or the Owner's designee to provide, or require to be provided, protection against harmful overpressure in such valves.

¹⁷ The severity and frequency of specified fluid temperature variations may be such that the period of calculated pressure integrity is less than plant design life. In such cases it is the responsibility of the Certificate Holder to state these conditions in the Design Report (NB-3560).

NB-3511 General Requirements^{16 17}

The requirements for design acceptability for valves shall be those given in this Subarticle. In all cases, pressure-temperature rating shall be as given in NB-3530 and, except for NB-3512.2(d) and in local regions (NB-3221.2), the wall thickness of the valve body shall not be less than that given by NB-3541. The requirements for prevention of nonductile fracture as set forth in NB-3211(d) shall be met. The requirements of NCA-3254(a) for specifying the location of valve boundary jurisdiction may be considered to have been met by employing the minimum limits of NB-1131, unless the Design Specification extends the boundary of jurisdiction beyond these minimum limits. The requirements of NCA-3254(b) for specifying the boundary conditions are not applicable to valve end connections.

NB-3512 Acceptability of Large Valves

Valve designs having an inlet piping connection larger than 4 in. nominal pipe size are acceptable when they satisfy

either the standard design rules or one of the alternative design rules.

NB-3512.1 Standard Design Rules.

The design shall be such that requirements of this Subarticle are met. The requirements of NB-3530 through NB-3550 apply to valves of conventional shape having generally cylindrical or spherical bodies with a single neck of a diameter commensurate with that of the main body portion, such as having a neck inside diameter less than twice the main run inside diameter in the neck region.

[98]

NB-3512.2 Alternative Design Rules.

A valve design may not satisfy all of the requirements of NB-3512.1.

Page 111

FIG. NB-3441.4(a)-1 TYPE D PUMP

FIG. NB-3441.4(a)-1 TYPE D PUMP

FIG. NB-3441.5-1 TYPE E PUMP

FIG. NB-3441.5-1 TYPE E PUMP

FIG. NB-3441.6(a)-1 TYPE F PUMP

FIG. NB-3441.6(a)-1 TYPE F PUMP

A design may be accepted provided it meets one of the alternatives listed in (a), (b), (c), or (d) below.

(a) When the valve design satisfies the rules of NB-3530 through NB-3546.2 with thermal stresses neglected, the rules of NB-3200 relative to accounting for thermal secondary stresses and fatigue analysis [NB-3222.2, NB-3222.3, and NB-3222.4] shall also be satisfied.

(b) When a valve is exempted from fatigue analysis by the rules of NB-3222.4(d), the design is acceptable, provided that the requirements of (1) or (2) below are met.

(1) The rules of NB-3530 through NB-3546 shall be met. The rules of NB-3200 may be substituted for those of NB-3545.2 for evaluating secondary stresses, and NB-3545.3 need not be considered.

(2) The rules of NB-3530 and NB-3541 shall be met. An experimental stress analysis is performed in accordance with Appendix II, and the rules of NB-3200 with respect to primary and secondary stresses resulting from pressure and mechanical loads shall be met. Unless otherwise specified in the Design Specifications, the pipe reactions shall be taken as those loads which produce a stress [NB-3545.2(b)] of 0.5 times the yield strength of the piping in tension for the direct or axial load and a stress of 1.0 times the yield strength of the piping in bending and torsion. Thermal secondary stresses shall be accounted for by either the rules of NB-3200 or NB-3545.

(c) When a valve design satisfies the rules of NB-3530 and NB-3541, and when an experimental stress analysis has been performed upon a similar valve in accordance with Appendix II, and an acceptable analytic method has been established, the results may be used in conjunction with the requirements of NB-3200 for pressure and mechanical loads to establish design acceptability. Accommodation of thermal secondary stresses and pipe reactions shall be as given in NB-3512.2(b)(2). Requirements for fatigue analysis of either NB-3200 or NB-3550 shall be met.

(d) When permitted by the Design Specification, a weld end valve that does not meet all of the requirements of NB-3540 may be designed so that it meets the requirements of NB-3200 for all pressure-retaining parts and those parts defined by NB-3546.3(a), and shall also meet all of the following requirements.

(1) Pressure, thermal, and mechanical effects, such as those resulting from earthquake, maximum stem force, closure force, assembly forces, and others that may be defined in the Design Specification, shall be included in the design analysis. For Level A Service Limits, the pipe reaction effects are to be determined by considering that the maximum fiber stress in the

Page 112

connected pipe is at one-half of its yield strength in direct tension and at its yield strength in torsion and in bending in the plane of the neck and run, and also in the plane of the run perpendicular to the neck, each considered separately. The individual pipe reaction effects that result in the maximum stress intensity at all points, including all other effects, shall be used for the analysis to satisfy the rules of NB-3200. The valve Design Specification shall provide the loadings and operating requirements to be considered under Level B, C, and D Service Limits [NCA-3252(a)(6)] for which a design analysis is to be included in the Design Report.

(2) In place of using the values of S_m to satisfy the rules of NB-3200, the allowable stress intensity values for ferritic valve body and bonnet materials shall be those allowable stress values given in Section II, Part D, Subpart 1, Table 1A. For materials in Section II, Part D, Subpart 1, Tables 2A and 2B, a reduced allowable stress intensity based on applying a factor of 0.67 to the yield strengths listed in Section II, Part D, Subpart 1, Table Y-1 shall be used.

(3) The adequacy of the stress analysis of the body and bonnet shall be verified by experimental stress analysis conducted in accordance with the requirements of II-1100 through II-1400. Individual tests shall be made to verify the adequacy of the stress analysis of internal pressure effects and pipe reaction effects. Tests shall be made on at least one valve model of a given configuration, but a verified analytical procedure may then be applied to other valves of the same configuration, although they may be of different size or pressure rating. The geometrical differences shall be accounted for in the extrapolation stress analysis. The analytical procedure shall have verified capability of providing this extrapolation.

(4) A Design Report shall be prepared in sufficient detail to show that the valve satisfies all applicable requirements.

(5) Prior to installation, the valve shall be hydro statically tested in accordance with NB-3531.2. For this purpose, the primary pressure rating shall be determined by interpolation in accordance with NB-3543(c).

[98]

NB-3513 Acceptability of Small Valves

Valve designs having an inlet piping connection 4 in. nominal pipe size or less are acceptable when they satisfy either the standard design rules or the alternative design rules.

NB-3513.1 Standard Design Rules.

The design shall be such that the requirements of NB-3530 and NB-3541 shall be met for wall thicknesses corresponding to the applicable pressure-temperature rating. When the Special Class Ratings of ANSI B16.34 apply, the NDE exemptions of NB-2510 shall not be used.

NB-3513.2 Alternative Design Rules.

A valve design shall satisfy the requirements of NB-3512.2.

NB-3515 Acceptability of Metal Bellows and Metal Diaphragm Stem Sealed Valves

Valves using metal bellows or metal diaphragm stem seals shall be constructed in accordance with the rules of this Subarticle, based on the assumption that the bellows or diaphragms do not retain pressure, and Design Pressure is imposed on a required backup stem seal such as packing. The bellows or diaphragms need not be constructed in accordance with the requirements of this Section.

NB-3520 DESIGN CONSIDERATIONS

NB-3521 Design and Service Loadings

The general design considerations of NB-3100 are applicable to valves. In case of conflict between NB-3100 and NB-3500, the requirements of NB-3500 shall apply.

NB-3524 Earthquake

The rules of this Subarticle consider that under earthquake loadings the piping system, not the valve, will be limiting and that the integrity of the valve pressure-retaining body is adequately considered under the piping requirements of NB-3600. Where valves are provided with operators having extended structures and these structures are essential to maintaining pressure integrity, an analysis, when required by the Design Specifications, may be performed based on static forces resulting from equivalent earthquake accelerations acting at the centers of gravity of the extended masses.

NB-3525 Levels A and B Service Limits

The design rules of NB-3512 and NB-3513 apply to loadings for which Level A or B Limits are designated except that when evaluating Level B Limits during operation of relief or safety valves (a) and (b) below shall be met.

(a) The service pressure may exceed the Design Pressures defined by the pressure-temperature ratings of ANSI B16.34 by no more than 10%.

Page 113

(b) The rules of NB-3540 apply using allowable stress intensity values of 110% of those listed in Section II, Part D, Subpart 1, Tables 2A and 2B.

NB-3526 Level C Service Limits

If the Design Specifications specify any loadings for which Level C Limits are designated, the rules used in evaluating these loadings shall be those of NB-3512 and NB-3513, except as modified by the following subparagraphs.

NB-3526.1 Pressure-Temperature Ratings.

The pressure permissible for loadings for which Level C Limits are designated shall not exceed 120% of that permitted for Level A Limits.

NB-3526.2 Pipe Reaction Stress.

Pipe reaction stresses shall be computed in accordance with the equations of NB-3545.2(b)(1), and the allowable value considered individually is $1.8S_m$ for the valve body material at 500°F (260°C). In performing these calculations, the value of S shall be taken as 1.2 times the yield strength at 500°F (260°C) of the material of the connected pipe, or 36.0 ksi when the pipe material is not defined in the Design Specifications.

NB-3526.3 Primary Stress and Secondary Stress.

The equation of NB-3545.2 shall be satisfied using C_p equal to 1.5, P_{ed} computed in accordance with NB-3526.2, and Q_T equal to 0, and the calculated value shall be limited to $2.25S_m$.

NB-3526.4 Secondary and Peak Stresses.

The requirements of NB-3545 and NB-3550 need not be met.

NB-3527 Level D Service Limits

If the Design Specifications specify any loadings for which Level D Limits are designated, the guidelines of Appendix F may be used in evaluating those loadings independently of other loadings.

NB-3530 GENERAL RULES

NB-3531 Pressure-Temperature Ratings and Hydrostatic Tests

NB-3531.1 Pressure-Temperature Ratings.

A valve designed in accordance with NB-3541 may be used in accordance with the pressure-temperature ratings in ANSI B16.34, Tables 2-1.1A to 2-2.7A (Standard Class) for flanged end or welding end (including socket welding end) valves, and ANSI B16.34, Tables 2-1.1B to 2-2.7B (Special Class) for welding end (including socket welding end) valves, provided the Design Pressure and Design Temperature are used. When a single valve has a flanged and a welding end, the flanged end requirements shall be used. The materials¹⁸ listed in ANSI B16.34, Table 1, may be used if listed in Section II, Part D, Subpart 1, Tables 2A and 2B, subject to the temperature limitations therein, and as defined in NCA-1220.

NB-3531.2 Hydrostatic Tests

(a) Valves designed in accordance with NB-3541 shall be subjected to the shell hydrostatic test pressures required by ANSI B16.34 and in accordance with other appropriate rules of NB-6000. Valves with a primary pressure rating less than Class 150 shall be subjected to the required test pressure for Class 150 rated valves.

(b) The shell hydrostatic test shall be made with the valve in the partially open position. Stem leakage during this test is permissible. End closure seals for retaining fluid at test pressure in welding end valves may be positioned in the welding end transitions, as defined in NB-3544.8(b), in reasonable proximity to the end plane of the valve so as to ensure safe application of the test pressure.

(c) After the shell hydrostatic test, a valve closure test shall also be performed with the valve in the fully closed position with a test pressure across the valve disk no less than 110% of the 100°F (38°C) pressure rating. For valves that are designed for Service Conditions that have the pressure differential across the closure member limited to values less than the 100°F (38°C) pressure rating, and have closure members or actuating devices (direct, mechanical, fluid, or electrical), or both, that would be subject to damage at high differential pressures, the test pressure may be reduced to 110% of the maximum specified differential pressure in the closed position. This exception shall be identified in the Design Specification, and this maximum specified differential pressure shall be noted on the valve name plate and N Certificate Holder's Data Report Form. During this test, seat leakage is permitted unless a limiting leakage value is defined by the Design Specifications. The duration of this test shall be 1 min/in. of minimum wall thickness t_m with a minimum duration of 1 min unless otherwise defined in the Design Specifications.

18 Special features such as wear surfaces or seating surfaces may demand special alloys or proprietary treatments. The absence of such materials from Section II, Part D, Subpart 1, Tables 2A and 2B shall not be construed to prohibit their use and such materials do not require approval under Appendix IV (NB-2121).

(d) For valves designed for nonisolation service, whose primary function is to modulate flow, and by

Page 114

their design are prevented from providing full closure, the valve closure test defined in (c) above is not required. This exception shall be identified in the Design Specification and noted on the valve nameplate and the N Certificate Holder's Data Report Form.

(e) Hydrostatic tests for metal bellows or metal diaphragm stem sealed valves shall include hydrostatic testing of the valve body, bonnet, body-to-bonnet joint, and either the bellows or diaphragm or the required backup stem seal.

(f) The inlet (primary pressure-containing) portion of pressure relief valves shall be hydrostatically tested at a pressure at least 1.5 times the set pressure marked on the valve. For closed system application, the outlet portion of the pressure relief valves shall be hydrostatically tested to 1.5 times the design secondary pressure (NB-7111).

NB-3531.3 Allowance for Variation From Design Loadings.

Under the conditions of relief or safety valve operation for valves designed in accordance with NB-3541, the service pressure may exceed the Design Pressure as defined by the pressure-temperature ratings of ANSI B16.34 by no more than 10%.

NB-3532 Design Stress Intensity Values

Design stress intensity values to be used in the design of valves are given in Section II, Part D, Subpart 1, Tables 2A and 2B.¹⁸

NB-3533 Marking

Each valve shall be marked as required by ANSI B16.34 and NCA-8220.

NB-3534 Nomenclature

A_f	= effective fluid pressure area based on fully corroded interior contour for calculating crotch primary membrane stress [NB-3545.1(a)], sq in.
A_m	= metal area based on fully corroded interior contour effective in resisting fluid force acting on A_f [NB-3545.1(a)], sq in.
C_a	= stress index for oblique bonnets [NB-3545.2(a)]
C_b	= stress index for body bending secondary stress resulting from moment in connected pipe [NB-3545.2(b)]
C_p	= stress index for body primary plus secondary stress, inside surface, resulting from internal pressure [NB-3545.2(a)]
C_1	= discontinuity temperature gradient index, °F/in. ²
C_2	= stress index for thermal secondary membrane stress resulting from structural discontinuity
C_3	= stress index for maximum secondary membrane plus bending stress resulting from structural discontinuity
C_4	= maximum magnitude of the difference in average wall temperatures for wall thicknesses T_{el} and t_e (resulting from a step change in fluid temperature ΔT_f) divided by ΔT_f
C_5	= stress index for thermal fatigue stress component resulting from through-wall temperature gradient caused by step change in fluid temperature (NB-3550)
C_6	= $E\alpha$ =product of Young's modulus and the coefficient of linear thermal expansion at 500°F, psi/°F (NB-3550)
C_7	= stress index for thermal stress resulting from through-wall temperature gradient associated with 100°F/hr fluid temperature change rate, psi/in.
d	= inside diameter used as a basis for crotch reinforcement [NB-3545.1(a)], in.
d_e	= inside diameter of the larger end of the valve body [NB-3545.2(b)(3)], in.

d_m	= inside diameter used as basis for determining body minimum wall thickness (NB-3541), in.
F_b	= bending modulus of standard connected pipe, in. ³
G_b	= valve body section bending modulus at crotch region [NB-3545.2(b)], in. ³
I	= moment of inertia, in. ⁴ , used in calculating G_b [NB-3545.2(b)(5)]
I_t	= fatigue usage factor for step changes in fluid temperature
K_e	= strain distribution factor used in elastic-plastic fatigue calculation (NB-3550)
$L_A L_N$	= effective distances used to determine $A_f A_m$ [NB-3545.1(a)(3)]
m, n	= material parameters for determining K_e (NB-3554)
N_a	= permissible number of complete startup/shutdown cycles at 100°F/hr fluid temperature change rate (NB-3545.3)
N_i	= permissible number of step changes in fluid temperature from Figs. I-9.0
N_{ri}	= required number of fluid step temperature changes ΔT_{fi} (NB-3553)
P_{eb}	= secondary stress due to pipe reaction [NB-3545.2(b)], psi

Page 115

P_m	= general primary membrane stress intensity at crotch region, calculated according to NB-3545.1(a), psi
p_d	= Design Pressure, psi
p_r	= Pressure Rating Class Index, psi
p_s	= standard calculation pressure from NB-3545.1, psi
p_1, p_2	= rated pressures from tables of ANSI B16.34 corresponding to Pressure Rating Class Indices p_{r1} and p_{r2} , psi
Q_p	= sum of primary plus secondary stresses at crotch resulting from internal pressure [NB-3545.2(a)], psi
Q_{T1}	= maximum thermal stress component caused by through-wall temperature gradient associated with 100°F/hr fluid temperature change rate [NB-3545.2(c)], psi
Q_{T3}	= maximum thermal secondary membrane plus bending stress resulting from structural discontinuity and 100°F/hr fluid temperature change rate, psi
r	= mean radius of body wall at crotch region [Fig. NB-3545.2(c)-1], in.
r_i	= inside radius of body at crotch region for calculating Q_p [NB-3545.2(a)], in.

r_2	= fillet radius of external surface at crotch [NB-3545.1 (a)], in.
S	= assumed maximum stress in connected pipe for calculating the secondary stress due to pipe reaction [NB-3545.2(b)], psi
S_i	= fatigue stress intensity range at crotch region resulting from step change in fluid temperature ΔT_{fi} and pressure ΔP_{fi} (NB-3550), psi
S_m	= design stress intensity (NB-3532), psi
S_n	= sum of primary plus secondary stress intensities at crotch region resulting from 100°F/hr temperature change rate (NB-3545.2), psi
$S_{n(max)}$	= maximum range of sum of primary plus secondary stress, psi
S_{p1}	= fatigue stress intensity at inside surface in crotch region resulting from 100°F/hr fluid temperature change rate (NB-3545.3), psi
S_{p2}	= fatigue stress intensity at outside surface in crotch region resulting from 100°F/hr fluid temperature change rate (NB-3545.3), psi
T_b	= thickness of valve wall adjacent to crotch region for calculating L_A and L_N [Fig. NB-3545.1(a)-1], in.
T_e	= maximum effective metal thickness in crotch region for calculating thermal stresses [Fig. NB-3545.2(c)-1], in.
T_r	= thickness of body (run) wall adjacent to crotch for calculating L_A and L_N [Fig. NB-3545.1(a)-1], in.
t_e	= minimum body wall thickness adjacent to crotch for calculating thermal stresses [Fig. NB-3545.2(c)-1], in.
t_m	= minimum body wall thickness as determined by NB-3541, in.
t_1, t_2	= minimum wall thicknesses from ANSI B16.34 corresponding to Listed Pressure Rating Class Indices p_{r1} and p_{r2} and inside diameter d_m , in.
ΔP_{fi}	= full range of pressure fluctuation associated with ΔT_{fi} , psi
ΔP_i	= specified range of pressure fluctuation associated with ΔT_i , psi
ΔT_{fi}	= a specified step change in fluid temperature, °F, where $i = 1, 2, 3, \dots, n$, used to determine the fatigue acceptability of a valve body (NB-3554)
ΔT_i	= specified range of fluid temperature, °F, where $i = 1, 2, 3, \dots, n$, used to evaluate normal valve usage (NB-3553)
ΔT	= maximum magnitude of the difference in average wall temperatures for walls of thicknesses t_e and T_e , resulting from 100°F/hr fluid temperature change rate, °F

NB-3540 DESIGN OF PRESSURE-RETAINING PARTS

NB-3541 General Requirements for Body Wall Thickness

The minimum wall thickness of a valve body is to be determined by the rules of NB-3542 or NB-3543.

19A listed pressure rated value is one listed in the tables of ANSI B16.34. A nonlisted pressure rated valve is one whose Design Pressure and Temperature do not specifically appear in those table (NB-3543).

NB-3542 Minimum Wall Thickness of Listed Pressure Rated Valves¹⁹

The wall thickness requirements for listed pressure rated valves apply also to integral body venturi valves. For a valve designed to a listed pressure rating of ANSI B16.34, the minimum thickness of its body wall, including the neck, is to be determined from ANSI B16.34, except that the inside diameter d_m shall be the larger of the basic valve body inside diameters in the region near the welding ends. Highly localized variations of inside diameter associated with weld preparation

Page 116

[NB-3544.8(a) and (b)] need not be considered for establishing minimum wall thickness t_m . In all such cases, however, the requirements of NB-3545.2(b)(6) shall be satisfied.

NB-3543 Minimum Wall Thickness of Valves of Nonlisted Pressure Rating¹⁹

To design a valve for Design Pressure and Design Temperature corresponding to other than one of the pressure ratings listed in the tables of ANSI B16.34, the procedure is the same as that of NB-3542 except that interpolation is required as follows.

(a) Based on the Design Temperature, linear interpolation between the tabulated temperature intervals shall be used to determine the listed pressure rating p_1 , next below, and p_2 , next above, the Design Pressure p_d corresponding to listed Pressure Rating Class Indices,²⁰ p_{r1} and p_{r2} respectively.

(b) Determine the minimum wall thickness t_m corresponding to Design Loadings by:

$$t_m = t_1 + \left(\frac{p_d - p_1}{p_2 - p_1} \right) \times (t_2 - t_1)$$

(c) Determine the interpolated Pressure Rating Class Index p_r , corresponding to Design Loadings, by:

$$p_r = p_{r_1} + \left(\frac{p_d - p_1}{p_2 - p_1} \right) \times (p_{r_2} - p_{r_1})$$

NB-3544 Body Shape Rules

The rules of this paragraph constitute minimum requirements intended to limit the fatigue strength reduction factor, associated with local structural discontinuities in critical regions, to 2.0 or less. When smaller values of the fatigue strength reduction factor can be justified, it is permissible to use them.

20For all listed pressure ratings except Class 150, the Pressure Rating Class Index is the same as the pressure rating class designation. For Class 150 use 115 psi for the Pressure Rating Class Index.

NB-3544.1 Fillets for External and Internal Intersections and Surfaces

(a) Intersections of the surfaces of the pressure retaining boundary at the neck to body junction shall be provided with fillets of radius $r_2 \geq 0.3t_m$. Figure NB-3544.1(a)-1 illustrates such fillets.

(b) Corner radii on internal surfaces with $r_4 < r_2$ are permissible.

(c) Sharp fillets shall be avoided. When sharp discontinuities are convenient for ring grooves and similar configuration details, they shall be isolated from the major body primary and secondary stresses or modified as illustrated by Fig. NB-3544.1(c)-1.

NB-3544.2 Penetrations of Pressure-Retaining Boundary.

Penetrations of the pressure-retaining boundary, other than the neck intersection, such as holes required for check valve shafts and drain or sensing lines, shall be located to minimize the compounding of normal body stresses.

NB-3544.3 Attachments.

Attachments, such as lugs and similar protuberances, on the pressure-retaining boundary shall be tapered to minimize discontinuity stresses (Fig. NB-3544.3-1). Reentrant angles shall be avoided. Attachments shall meet the requirements of NB-3135.

NB-3544.4 Body Internal Contours.

Body internal contours in sections normal to the run or neck center lines shall be generally smooth in curvature, or so proportioned that the removal of unavoidable discontinuities, such as the valve seat, will leave generally smooth curvature.

NB-3544.5 Out-of-Roundness.

Out-of-roundness in excess of 5% for sections of essentially uniform thickness shall be such that:

$$\frac{b}{t_b} + \frac{3}{4} \left(\frac{3b^2 - 2ab - a^2}{t_b^2} \right) + 1 \leq 1.5 \left(\frac{S_m}{p_s} \right)$$

where

$2a$	= minor inside diameter, in.
$2b$	= major inside diameter, in.
t_b	= thickness, in.

The ovality criterion can be satisfied by increasing the thickness locally, provided that the thickness variation is smoothly distributed. Out-of-roundness in excess of this limitation must be compensated for by providing reinforcement.

NB-3544.6 Doubly Curved Sections.

Sections curved longitudinally with radius r_{Long} as well as laterally with radius r_{Lat} must be such that:

Page 117

FIG. NB-3544.1(a)-1 FILLETS AND CORNERS

FIG. NB-3544.1(a)-1 FILLETS AND CORNERS

$$r_3 \geq \begin{cases} 0.05 t_m \\ 0.1 h \end{cases} \text{ whichever is greater}$$

FIG. NB-3544.1(c)-1 RING GROOVES

FIG. NB-3544.1(c)-1 RING GROOVES

FIG. NB-3544.3-1 LUGS AND PROTUBERANCES

FIG. NB-3544.3-1 LUGS AND PROTUBERANCES

$$\frac{1}{r_{\text{Long}}} + \frac{1}{r_{\text{Lat}}} \geq \frac{4}{3d_m}$$

where d_m is the diameter used to establish the local wall thickness by NB-3541.

NB-3544.7 Flat Sections.

Flat sections shall be sufficiently limited in extent so that arcuate sections having the same radius-thickness ratio as required by NB-3542 may be inscribed (Fig. NB-3544.7-1). The inscribed section may be less thick than the minimum thickness required by NB-3542, provided that its radius is proportionally smaller than the value used to determine the minimum required thickness. The method of NB-3544.6 above may be used to show additive support, but the denominator of the right side term must be reduced in the ratio of the thickness of the inscribed arcuate section to the minimum required thickness (NB-3542). If adequacy cannot be shown by the above rules, it is necessary to determine the stresses in the flat region experimentally to demonstrate adequacy for pressure induced stresses only, with internal pressure equal to the standard calculation pressure p_s .

NB-3544.8 Body End Dimensions

(a) Valve body contours at valve weld ends shall be in accordance with Fig. NB-4250-1, and, unless otherwise stated in the Design Specifications, with ANSI B16.34.

(b) Valve body transitions leading to valve weld ends shall be in accordance with ANSI B16.34.

(c) Flanged ends shall be in accordance with ANSI B16.34.

(d) Alignment tolerances given in Fig. NB-4233(a)-1 shall apply to all auxiliary piping, such as drain lines, which begin or terminate at the valve.

(e) For socket welding ends, valves of nominal size 2 in. (DN 50) and smaller for which the body cavity consists of cylindrically bored sections shall meet all of the following:

- (1) d_m shall be the port drill diameter;
- (2) the requirements of NB-3542 shall be satisfied; and
- (3) socket welding end valves of nominal size greater than 2 in. (DN 50) shall not be used.

NB-3544.9 Openings for Auxiliary Connections.

Openings for auxiliary connections, such as for drains, bypasses, and vents, shall meet the requirements of ANSI B16.34 and the applicable reinforcement requirements of NB-3330.

NB-3545 Body Primary and Secondary Stress Limits

The limits of primary and secondary stresses are established in the following subparagraphs.

NB-3545.1 Primary Membrane Stress Due to Internal Pressure.

For valves meeting all requirements of this Subarticle, the most highly stressed portion of the body under internal pressure is at the neck to flow passage junction and is characterized by circumferential tension normal to the plane of center lines, with the maximum value at the inside surface. The rules of this paragraph are intended to control the general primary membrane stress in this crotch region. The Standard Calculation Pressure p_s to be used for satisfying the requirements of NB-3545 is found either directly or by interpolation from the tables in ANSI B16.34 as the pressure at 500°F (260°C) for the given Pressure Rating Class Index p_r .

(a) In the crotch region, the maximum primary membrane stress is to be determined by the pressure area method in accordance with the rules of (1) through (6) below using Fig. NB-3545.1(a)-1.

(1) From an accurately drawn layout of the valve body, depicting the finished section of the crotch region in the mutual plane of the bonnet and flow passage center lines, determine the fluid area A_f and metal area A_m . A_f and A_m are to be based on the internal surface after complete loss of metal assigned to corrosion allowance.

(2) Calculate the crotch general primary membrane stress intensity:

$$P_m = \left(\frac{A_f}{A_m} + 0.5 \right) p_s$$

The allowable value of this stress intensity is S_m for the valve body material at 500°F (260°C) as given in Section II, Part D, Subpart 1, Tables 2A and 2B.

(3) The distances L_A and L_N which provide bounds on the fluid and metal areas are determined as follows. Use the larger value of:

Page 120

Page 122

Pages 121-121

FIG. NB-3545.1(a)-1 PRESSURE AREA METHOD

FIG. NB-3545.1(a)-1 PRESSURE AREA METHOD

FIG. NB-3545.1(a)-1 PRESSURE AREA METHOD (CONT'D)

FIG.NB-3545.1(a)-1 PRESSURE AREA METHOD (CONT'D)

$$L_A = 0.5d - T_b$$

OR

$$L_A = T_r$$

and use

$$L_N = 0.5r_2 + 0.354 \sqrt{T_b(d + T_b)}$$

where the dimensions are as shown in Fig. NB-3545.1(a)-1.

In establishing appropriate values for the above parameters, some judgment may be required if the valve body is irregular as it is for globe valves and others with nonsymmetric shapes. In such cases, the internal boundaries of A_f shall be the lines that trace the greatest width of internal wetted surfaces perpendicular to the plane of the stem and pipe ends [Fig. NB-3545.1(a)-1 sketches (b), (d), and (e)].

(4) If the calculated boundaries for A_f and A_m as defined by L_A and L_N fall beyond the valve body [Fig. NB-3545.1(a)-1 sketch (b)], the body surface becomes the proper boundary for establishing A_f and A_m . No credit is to be taken for any area of connected piping which may be included within the limits of L_A and L_N . If the flange is included with A_m , the area of one bolt hole is to be subtracted for determining the net value of A_m .

(5) Except as modified below, web or fin-like extensions of the valve body are to be credited to A_m only to an effective length from the wall equal to the average thickness of the credited portion. The remaining web area is to be added to A_f [Fig. NB-3545.1(a)-1 sketch (b)]. However, to the extent that additional area will pass the following test, it may also be included in A_m . A line perpendicular to the plane of the stem and pipe ends from any points in A_m does not break out of the wetted surface but passes through a continuum of metal until it breaks through the outer surface of the body.

(6) In most cases, it is expected that the portions defined by A_m in the several illustrations of Fig. NB-3545.1(a)-1 will be most highly stressed. However, in the case of highly irregular valve bodies, it is recommended that all sections of the crotch be checked to ensure that the largest value of P_m has been established considering both open and fully closed conditions.

(b) In regions other than the crotch, while the value of P_m calculated by NB-3545.1(a) will be the highest value of body general primary membrane stress for all normal valve types with typical wall proportioning, the designer is cautioned to review unusual body configurations for possible higher stress regions. Suspected regions are to be checked by the pressure area method applied to the particular local body contours. The allowable value of this stress intensity is S_m for the valve body material at 500°F (260°C) as given in Section II, Part D, Subpart 1, Tables 2A and 2B.

NB-3545.2 Secondary Stresses.

In addition to satisfying the criteria of NB-3541 through NB-3545.1, a valve body shall also satisfy the criterion that the range of primary plus secondary stresses S_n due to internal pressure, pipe reaction, and thermal effects shall not exceed $3 S_m$ for the body material at 500°F (260°C), where Q_p , P_{eb} , and Q_{T3} are determined by the rules of this paragraph. That is:

$$S_n = Q_p + P_{eb} + 2 Q_{T_3} \leq 3 S_m$$

(a)(1) The body primary plus secondary stress Q_p due to internal pressure is to be determined by:

$$Q_p = C_p \left(\frac{r_i}{t_e} + 0.5 \right) p_s$$

where the primary plus secondary pressure stress index C_p is equal to 3 and

p_s	= Standard Calculation Pressure defined by NB-3545.1, psi
r_i	= radius of a circle which circumscribes the inside wall contour in the crotch region, in.
t_e	= an effective wall thickness at that location, in. (typically $t_e = T_r$) [Fig. NB-3545.1(a)-1]

In choosing an appropriate value for t_e , credit may be taken for general reinforcement material at the critical section but not for local fillets. Protuberances or ribs are not to be considered in determining r_i and t_e . Guidance is provided by Fig. NB-3545.2(a)-1 in which the illustrations correspond to the critical sections of the valve bodies of Fig. NB-3545.1(a)-1. The parameters r_i and t_e are intended to be representative of a tee, reinforced or unreinforced, with the general configuration of the valve body for which minor shape details associated with the valve function are ignored.

(2) For valve bodies with bonnet center lines other than perpendicular to the flow passage, the body stress Q_p due to internal pressure defined above must be multiplied by the factor C_a :

Page 123

Page 124

FIG. NB-3545.2(a)-1 CRITICAL SECTIONS OF VALVE BODIES

FIG. NB-3545.2(a)-1 CRITICAL SECTIONS OF VALVE BODIES

$$C_a = 0.2 + \frac{0.8}{\sin \alpha}$$

where

α = acute angle between the bonnet and flow passage center lines, deg.

(b) The secondary stress due to pipe reaction shall meet the criteria of (1) through (6) below to ensure the adequacy of the valve body for safely transmitting forces and moments imposed by the connected piping system.

(1) Based on the critical section A-A at the crotch, as illustrated by Fig. NB-3545.2(a)-1, calculate the value of P_{eb} where

(Bending load effect)

$$P_{eb} = \frac{C_b F_b S}{G_b}$$

The allowable value of P_{eb} is $1.5S_m$ for the valve body material at 500°F (260°C). Determination of S , F_b , C_b , and G_b required to calculate P_{eb} is to be in accordance with the requirements of (2) through (5) below.

(2) When the valve designer knows the material of the connected pipe, S may be calculated as the yield strength for the pipe material at 500°F (260°C). When the designer does not know the piping material or is designing a valve independently of a particular application, the value of S shall be taken as 30.0 ksi (207 MPa).

(3) Calculate F_b where

$$F_b = \frac{0.393 d_e^3 p_s}{20,000 - p_s}$$

but not less than:

(a) the section modulus of Schedule 40 pipe with the next larger inside diameter than d_e for $d_e < 10.02$ in.

(b) $0.295 d_e^2$ for $d_e > 10.02$ in. where d_e equals the inside diameter of the larger end of the valve body.

(4) Calculate the factor C_b :

$$C_b = 0.335 \left(\frac{r}{t_e} \right)^{2/3}$$

When the results are less than 1.0, use $C_b = 1.0$.

(5) The factor G_b is the section modulus $I/(r_i + t_e)$, in.³, for bending at the plane through A-A about the axis perpendicular to the mutual plane of bonnet and body center lines, such as that axis which produces maximum bending stress at the corner of the crotch. The fiber stress at the outside surface is to be considered as governing in calculating G_b .

(6) When valves are to be applied in a venturi arrangement such that the connected pipe may be larger than that corresponding to the nominal size of the valve, it is necessary to base P_{eb} on the actual larger connected pipe. Such cases must be treated individually to ensure compliance with the secondary and fatigue stress criteria of this Subarticle.

When the venturi arrangement is not fabricated by the N Certificate Holder, the Design Specifications shall include sufficient information to permit the N Certificate Holder to make this check.

(c) Thermal secondary stresses in the valve crotch region, resulting from through-wall temperature gradient and thickness variation (average temperature difference), are to be calculated on the basis of a continuous ramp change in fluid temperature at 100°F/hr (56°C/hr) using the model of Fig. NB-3545.2(c)-1 sketch (a). Figure NB-3545.2(c)-1 sketch (b) illustrates how r , T_{e1} , T_{e2} and t_e are to be determined for the typically irregular crotch shape of valves. The thermal secondary stress components are to be determined in accordance with the following:

(1) Stress component Q_{T1} which is the result of a through-wall temperature gradient is defined as:

$$Q_{T1} = C_7 (T_{e1})^2$$

where

$$\begin{array}{ll} C_7 & = 110 \text{ psi/in.}^2 \text{ for ferritic steels, or} \\ C_7 & = 380 \text{ psi/in.}^2 \text{ for austenitic steels} \end{array}$$

T_{e1} is illustrated in Fig. NB-3545.2(c)-1.

(2) Stress component Q_{T3} which is the membrane plus bending stress as a result of wall thickness variation is defined as:

$$Q_{T3} = C_6 C_3 \Delta T'$$

where C_3 is found from Fig. NB-3545.2(c)-4 and

$$\Delta T' = C_1 (T_{e1}^2 - t_e^2)$$

where

$$C_1 = \begin{cases} .53 \text{ } ^\circ\text{F/in.}^2 & \text{for ferritic steels, or} \\ 1.4 \text{ } ^\circ\text{F/in.}^2 & \text{for austenitic steels} \end{cases}$$

t_e is illustrated in Fig. NB-3545.2(c)-1.

NB-3545.3 Fatigue Requirements.

The fatigue analysis requirements are satisfied provided the rules of this subparagraph and the rules of NB-3550 are met.

Page 125

Page 126

FIG. NB-3545.2(c)-1 MODEL FOR DETERMINING SECONDARY STRESS IN VALVE CROUCH REGION

FIG. NB-3545.2(c)-3 THERMAL STRESS INDEX VERSUS THICKNESS CONTINUITY RUN OR BRANCH

FIG. NB-3545.2(c)-4 SECONDARY STRESS INDEX VERSUS THICKNESS DISCONTINUITY RUN OR BRANCH

FIG. NB-3545.2(c)-5 C_4 VERSUS T_{e1}/t_e

FIG. NB-3545.2(c)-5 C_4 VERSUS T_{E1}/t_e

FIG. NB-3545.2(c)-6 STRESS INDEX FOR THERMAL FATIGUE

FIG. NB-3545.2(c)-6 STRESS INDEX FOR THERMAL FATIGUE

The calculated allowable number of cycles is $N_a \geq 2000$ cycles, where N_a is determined from Figs. I-9.0 by entering the appropriate curve with S_a with S_a defined as the larger value of S_{p1} and S_{p2} defined as follows:

$$S_{p1} = \frac{2}{3} Q_p + \frac{P_{eb}}{2} + Q_{T3} + 1.3 Q_{T1}$$

$$S_{p_2} = 0.4Q_p + \frac{K}{2} (P_{eb} + 2Q_{T_3})$$

The values of S_{p_1} and S_{p_2} are based on the values for Q_p , P_{eb} , Q_{T_1} , and Q_{T_3} found in accordance with the rules of NB-3545.2. K is the fatigue strength reduction factor associated with the external fillet at the crotch and is to be considered as 2.0 unless the designer can justify use of a smaller value.

NB-3546 Design Requirements for Valve Parts Other Than Bodies

NB-3546.1 Body-to-Bonnet Joints

(a) Bolted body-to-bonnet joints shall be designed in accordance with the pressure design rules of XI-3000, including the use of the appropriate allowable stress given in Section II, Part D, Subpart 1, Tables 1A and 1B, or by the procedures of NB-3200, except fatigue analysis of bolts is not required.

(b) Body-to-bonnet joints other than bolted connections including joints of special or patented types for which specific standards do not exist may be used provided that the N Certificate Holder shall use methods of design and construction that will be as safe as otherwise required by the rules of this Subarticle for the following design conditions:

(1) Design Pressure equal to Standard Calculation Pressure p_s (NB-3545.1);

(2) calculation temperature of 500°F (260°C);

(3) thermal stresses based on most severe conditions resulting from continuous fluid temperature ramp increase or decrease at 100°F/hr (56°C/hr);

(4) fatigue life at least 2000 cycles of startup/shutdown based on the above conditions with simultaneous increase or decrease of pressure and temperature.

NB-3546.2 Valve Disk.

The valve disk shall be considered a part of the pressure-retaining boundary. The primary membrane stress intensity shall not exceed S_m , and the primary bending stress intensity shall not exceed $1.5S_m$.

NB-3546.3 Other Valve Parts

(a) Valve stems, stem retaining structures, and other significantly stressed valve parts whose failure can lead to gross violation of the pressure-retaining boundary shall be designed so that their primary stresses, based on pressure equal to the 100°F (38°C) pressure rating and conservatively estimated or calculated additional loadings, where applicable, do not exceed S_m as tabulated in Section II, Part D, Subpart 1, Tables 2A and 2B, or for materials not listed in these Tables, do not exceed two-thirds of the minimum specified yield strength or one-fourth of the minimum specified tensile strength, whichever is lower.

(b) Bypass piping shall be designed in accordance with the requirements of NB-3600. Unless otherwise stated in the

valve Design Specifications, bypass piping design shall be the responsibility of the piping system designer.

(c) Valve designs, requiring solenoid plunger core tubes or electromagnetic position indicator core tubes, may substitute the rules of NB-3641.1 for the requirements of NB-3541, NB-3542, or NB-3543 for minimum wall thickness of the extension, provided that detailed calculations are prepared in accordance with NB-3200 at the 100°F (38°C) valve pressure rating conditions, and covering all discontinuities in the core tube, including the cap end and attachment end, and all welds, including any dissimilar metal welds. These calculations shall be included in the Design Report (NB-3560). The calculations shall include the design loadings given in NB-3546.1(b)(1) through NB-3546.1(b)(4) along with any additional requirements given in the Design Specifications.

NB-3546.4 Fatigue Evaluation.

When the Design Specifications include such service loadings that the valve is not exempted from fatigue analysis by the rules of NB-3222.4(d), it is recommended that consideration be given to the cyclic stress duty of the portions considered by NB-3546.

NB-3550 CYCLIC LOADING REQUIREMENTS

NB-3551 Verification of Adequacy for Cyclic Conditions

The adequacy of a valve for cyclic loading shall be verified in accordance with this Subsubarticle. Nonintegral seat rings attached to the valve body by partial penetration or fillet welds (NB-4433) are exempt from the fatigue analysis requirements of NB-3123.2, provided

Page 130

the seat rings are shouldered against the valve body; see Fig. NB-3544.1(c)-1.

NB-3552 Excluded Cycles

In satisfying the cyclic loading requirements, the following variations need not be considered:

- (a) pressure variations less than $p_d/3$ for carbon and low alloy steels and less than $p_d/2$ for austenitic stainless steels;
- (b) temperature variations less than 30°F (17°C);
- (c) accident or maloperation cycles expected to occur less than five times (total) during the expected valve life;
- (d) startup, shutdown cycles with temperature change rates of 100°F/hr (56°C/hr) or less, not in excess of 2000.

NB-3553 Fatigue Usage

The application of a valve conforming to NB-3512.1 is acceptable for cyclic loading conditions provided its fatigue usage I_f is not greater than 1.0 as evaluated in (a), (b), and (c) below.

(a) Consider fluid temperature changes not excluded by NB-3552 to occur instantaneously. Provided that these changes occur in one direction and recovery is at temperature change rates not in excess of 100°F/hr (56°C/hr), the fatigue usage factor may be found by:

$$I_i = \sum \frac{N_{ri}}{N_i}$$

where N_{ri} is the required or estimated number of fluid temperature step changes ΔT_{fi} and N_i is found from Figs. I-9.1 and I-9.2.

(b) If both heating and cooling effects are expected at change rates exceeding 100°F/hr (56°C/hr), the number of cycles are to be associated by temperature ranges ΔT_i . For example, assuming the following variations are specified:

20 variations $\Delta T_1 = 250$ heating

10 variations $\Delta T_2 = 150$ cooling

100 variations $\Delta T_3 = 100$ cooling

lump the ranges of variation so as to produce the greatest effects as follows:

10 cycles ΔT_{f1} = 250 + 150 = 400

10 cycles ΔT_{f2} = 250 + 100 = 350

90 cycles ΔT_{f3} = 100

(c) Pressure fluctuations not excluded by NB-3552 are to be included in the cyclic load calculations. The full range of pressure fluctuation from the normal condition to the condition under consideration shall be represented by Δp_i in NB-3554.

NB-3554 Cyclic Stress Calculations

A valve conforming to NB-3512.1 shall be qualified by the procedure of (a) through (d) below.

(a) The following criterion shall be met by the greatest temperature range:

$$Q_p [\Delta p_{f(\max)} / p_s] + C_6 C_2 C_4 \Delta T_{f(\max)} < 3 S_m$$

where $\Delta T_{f(\max)}$ is the largest lumped temperature range obtained using the methods of NB-3553(b), and $\Delta p_{f(\max)}$ is the largest range of pressure fluctuation associated with $\Delta T_{f(\max)}$.

(b) Calculate:

$$S_{n(\max)} = Q_p [\Delta p_{f(\max)} / p_s] + C_6 C_3 C_4 \Delta T_{f(\max)}$$

Provided that $S_{n(\max)} \leq 3S_m$, calculate the fatigue stresses for each cyclic loading condition as follows:

$$S_i = \sqrt[4]{3} Q_p (\Delta p_{fi} / p_s) + C_6 (C_3 C_4 + C_5) \Delta T_{fi}$$

Determine the allowable number of cycles N_i for each loading condition by entering Figs. I-9.1 and I-9.2 with $S_i/2$, and determine the fatigue usage by NB-3553(a).

(c) If $S_{n(\max)}$ is greater than $3S_m$ but less than $3mS_m$, the value of $S_i/2$ to be used for entering the design fatigue curve is to be found by multiplying S_i by K_e , where:

$$K_e = 1.0 + \frac{(1 - n)}{n(m - 1)} \left(\frac{S_n}{3S_m} - 1 \right)$$

and where the values of the material parameters m and n are as given in Table NB-3228.5(b)-1.

(d) If $S_{n(\max)}$ is greater than $3mS_m$, use $K_e = 1/n$.

NB-3560 DESIGN REPORTS

NB-3561 General Requirements

The certified Design Reports listed in this paragraph meet the requirements of NCA-3550 for the Design Report.

Page 131

NB-3562 Design Report for Valves Larger Than 4 in. Nominal Pipe Size (DN 100)

A Design Report shall be prepared in sufficient detail to show that the valve satisfies the requirements of NB-3512. For a valve designed in accordance with NB-3512.1, the Design Report shall show that the applicable requirements of NB-3530, NB-3541 through NB-3546.2, and NB-3550 have been met. It is not necessary to write a special Design Report based on specified Design Pressure and Design Temperature when they are within the pressure-temperature rating and when supplementary information or calculations are also provided, as necessary, to complete the report for a specific application, such as the thermal cyclic duty evaluation of NB-3550. A report submitted demonstrating a design for loadings more severe than the specified loadings is also acceptable.

NB-3563 Design Report Requirements for 4 in. and Smaller Nominal Pipe Size ($\leq$ DN 100) Valves

For valves whose inlet piping connection is nominally 4 in. (DN 100) or smaller, the Design Report shall include details to show that the requirements of NB-3513 have been met.

NB-3590 PRESSURE RELIEF VALVE DESIGN

NB-3591 Acceptability

NB-3591.1 General.

The rules of this Subsubarticle constitute the requirements for the design acceptability of spring-loaded pressure relief valves. The design rules for pilot operated and power actuated pressure relief valves are covered by NB-3500. The rules of this Subsubarticle cover the pressure-retaining integrity of the valve inlet and outlet connections, nozzle, disk, body structure, bonnet (yoke), and body-to-bonnet (yoke) bolting. The rules of this Subsubarticle also cover other items such as the spring, spindle (stem), spring washers, and set pressure adjusting screw. The rules of this Subsubarticle do not apply to guides, control ring, bearings, set screws, and other nonpressure-retaining items. Figures NB-3591.1-1 and NB-3591.1-2 are illustrations of typical pressure relief valves.

NB-3591.2 Definitions.

The definitions for pressure relief valve terms used in this Subsubarticle are given in ANSI B95.1, Terminology for Pressure Relief Devices, and also in NB-7000. Pressure relief valves characteristically have multipressure zones within the valve, that is, a primary pressure zone and a secondary pressure zone as illustrated by Figs. NB-3591.1-1 and NB-3591.1-2.

NB-3591.3 Acceptability of Small Liquid Relief Valves.

Liquid pressure relief valves meeting the requirements of NB-7000 and having an inlet piping connection 2 in. nominal pipe size (DN 50) and under shall comply with the minimum wall thickness requirements of NB-3542 or NB-3543 for the applicable pressure zone. Flange end ratings of NB-3531.1 shall be used regardless of end connection. The applicable design requirements of this Subsubarticle covering the nozzle, disk, and bonnet shall apply. The analyses of NB-3544, NB-3545, and NB-3550 do not apply.

NB-3591.4 Acceptability of Safety and Safety Relief Valves.

The design shall be such that the requirements of this Subsubarticle are met.

NB-3592 Design Considerations

NB-3592.1 Design Conditions.

The general design requirements of NB-3100 are applicable, with consideration for the design conditions of the primary and secondary pressure zones. The design pressure of the Design Specification shall be used for the applicable zones.

In case of conflict between NB-3100 and NB-3590, the requirements of NB-3590 shall apply. Mechanical loads for both the closed and the open (full discharge) positions shall be considered in conjunction with the service conditions. In addition, the requirements of NB-7000 shall be met.

NB-3592.2 Stress Limits for Specified Service Loadings

(a) Stress limits for Level A and B Service Loadings shall be as follows:

- (1) the primary membrane stress intensity shall not exceed S_m ;
- (2) the primary membrane stress intensity plus primary bending stress intensity shall not exceed $1.5S_m$;
- (3) substantiation by analysis of localized stresses associated with contact loading of bearing or seating surfaces is not required;
- (4) the values of S_m shall be in accordance with Section II, Part D, Subpart 1, Tables 2A, 2B, and 4.

(b) Stress limits for Level C Service Loadings shall be as follows:

- (1) the primary membrane stress intensity shall not exceed $1.5S_m$;

Page 132

Page 133

FIG. NB-3591.1-1 TYPICAL PRESSURE RELIEF DEVICES

FIG. NB-3591.1-2 TYPICAL PRESSURE RELIEF AND SAFETY RELIEF DEVICES

FIG. NB-3591.1-2 TYPICAL PRESSURE AND SAFETY RELIEF DEVICES

- (2) the primary membrane stress intensity plus primary bending stress intensity shall not exceed $1.8S_m$ (NB-3526.2);
- (3) the rules of NB-3526.3 must be satisfied.
- (c) Stress limits for Level D Service Loadings shall be as follows:
 - (1) the guidelines of Appendix F may be used in evaluating these conditions.
 - (d) These requirements for the acceptability of valve design are not intended to ensure the functional adequacy of the valve. However, the Designer is cautioned that the requirements of NB-7000 relative to set pressure, lift, blowdown, and closure shall be met.

NB-3592.3 Earthquake.

The rules of this Subsubarticle consider that under earthquake loadings the piping system or vessel nozzle, rather than the valve body, will be limiting. Pressure relief valves have extended structures and these structures are essential to maintaining pressure integrity. An analysis, when required by the Design Specification, shall be performed based on static forces resulting from equivalent earthquake acceleration acting at the centers of gravity of the extended masses. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, may be used.

NB-3593 Special Design Rules

NB-3593.1 Hydrostatic Test.

Hydrostatic testing shall be performed in accordance with NB-3531.2(f).

NB-3593.2 Marking.

In addition to the marking required by NCA-8220 and NB-7000, the secondary Design Pressure shall be marked on the valve or valve nameplate.

NB-3594 Design of Pressure Relief Valve Parts

NB-3594.1 Body.

The valve body shall be analyzed with consideration for the specific configuration of the body and the applicable pressure zone and loadings. The design shall take into consideration the adequacy of the inlet flange connection, the outer flange connection, and the body structural configuration. In valve designs where the outlet flange is an extension of the bonnet, the bonnet design shall conform to all rules of body design. The body shall be designed in accordance with the rules of NB-3540 through NB-3550. The design adequacy of the inlet and outlet flanges shall be determined using the rules of NB-3658. Flanges shall conform to the applicable pressure-temperature ratings of NB-3531.1 and shall meet the interface dimensions of ANSI B16.5.

NB-3594.2 Bonnet (Yoke).

The bonnet (yoke) may be analyzed using classic bending and direct stress formulae, with appropriate free body diagrams. The general primary membrane stress intensity and the general primary membrane plus primary bending stress intensity shall be determined and shall not exceed the stress limits of NB-3592.2.

NB-3594.3 Nozzle.

The nozzle shall be analyzed in accordance with the applicable rules of NB-3540 and NB-3550, with a basic analytical model configuration as shown in Fig. NB-3594.3-1. The sections of the nozzle where dimensions are limited by the flow capacity and the operational control requirements may be considered as simple cylindrical sections. The minimum wall thickness of these sections shall be determined in accordance with NB-3324.1. These requirements are not applicable to the transition region to the seat contacting area of the nozzle, defined by L in Fig. NB-3594.3-1, provided dimension L is less than the nominal wall thickness t_1 .

NB-3594.4 Body-to-Bonnet Joint.

The body-to-bonnet joint shall be analyzed in accordance with NB-3546.1.

NB-3594.5 Disk.

The valve disk shall satisfy the requirements of NB-3546.2.

NB-3594.6 Spring Washer.

The average shear stress shall not exceed $0.6S_m$. The primary bending stress intensity shall not exceed the stress limits of NB-3592.2.

NB-3594.7 Spindle (Stem).

The general primary membrane stress intensity shall not exceed the stress limits of NB-3592.2.

NB-3594.8 Adjusting Screw.

The adjusting screw shall be analyzed for thread shear stress in accordance with the method of ANSI B1.1 and this stress shall not exceed $0.6S_m$. The general primary membrane stress intensity of the adjusting screw shall not exceed the stress limits of NB-3592.2, based on the root diameter of the thread.

NB-3594.9 Spring.

The valve spring shall be designed so that the full lift spring compression shall be no greater than 80% of the nominal solid deflection. The permanent set of the spring (defined as the difference between the free height and height measured a minimum of 10 min after the spring has been compressed solid three additional times after presetting at

Page 135

room temperature) shall not exceed 0.5% of the free height.

- t_1, t_2 = nozzle wall thickness, in.
 t_e = minimum body wall thickness adjacent to crotch, in.
 T_{e1} = maximum effective thickness in crotch region, in.
 T_{e2} = effective crotch wall thickness, in.
 r_1 = inside radius at crotch region, in.
 r_2 = outside fillet radius at crotch
 L = length of seat transition region, in.
 A_f = fluid area, in.²
 A_m = metal area, in.²

[98]

FIG. NB-3594.3-1 VALVE NOZZLE

NB-3595 Design Report

NB-3595.1 General Requirements.

A Design Report shall be prepared in sufficient detail to show that the valve satisfies the rules of this Subsubarticle and NCA-3550.

NB-3600 PIPING DESIGN

NB-3610 GENERAL REQUIREMENTS

NB-3611 Acceptability

The requirements for acceptability of a piping system are given in the following subparagraphs.

NB-3611.1 Stress Limits.

The design shall be such that the stresses will not exceed the limits described in NB-3630 except as provided in NB-3611.2.

Page 136

NB-3611.2 Acceptability When Stresses Exceed Stress Limits.

When the stresses as determined by the methods given in NB-3630 exceed the limits thereof, the design can be accepted, provided it meets the requirements of NB-3200. The rules of NB-3630 meet all the requirements of NB-3200.

NB-3611.3 Conformance to NB-3600.

In cases of conflict between NB-3100 and NB-3600, the requirements of NB-3600 shall apply.

NB-3611.4 Dimensional Standards.

For the applicable year of issue of all dimensional standards referred to in NB-3600, see Table NB-3132-1.

NB-3611.5 Prevention of Nonductile Fracture.

The requirements for prevention of nonductile fracture as set forth in NB-3211(d) shall be met.

NB-3612 Pressure-Temperature Ratings

NB-3612.1 Standard Piping Products

(a) When standard piping products are used, the pressure ratings given as functions of temperature in the appropriate standards listed in Table NB-3132-1 shall not be exceeded. In addition, the requirements of NB-3625 shall be met. When established pressure ratings of standard products do not extend to the upper temperature limits for the material, the ratings between those established and the upper temperature limit may be determined in accordance with NB-3649.

(b) When the adequacy of the pressure design of a standard product is established by burst tests as permitted in NB-3649 (ANSI B16.9, Section 8), the manufacturer of the product shall maintain a record of burst tests conducted to ensure adequacy of product and shall so certify. Such records shall be available to the purchaser.

NB-3612.2 Piping Products Without Specific Ratings.

If piping products are used for which methods of construction are not covered by this Subsection, the manufacturer of the product shall use methods of construction that will be as safe as otherwise provided by the rules of this Subsection. When products are used for which pressure-temperature ratings have not been established by the standards listed in Table NB-3132-1, the products shall be designed and tested in accordance with NB-3640. The manufacturer's recommended pressure-temperature ratings shall not be exceeded.

NB-3612.4 Considerations for Local Conditions and Transients

(a) When piping systems operating at different pressures are connected by a valve or valves, the valve or valves shall be designed for the higher pressure system requirements of pressure and temperature. The lower pressure system shall be designed in accordance with (1), (2), or (3) below.

(1) The requirements of the pressure system shall be met.

(2) Pressure relief devices or safety valves shall be included to protect the lower pressure system in accordance with

NB-7311.

(3) Ensure compliance with all the conditions of (a) through (e) below.

(a) Redundant check or remote actuated valves shall be used in series at the interconnection, or a check in series with a remote actuated valve.

(b) When mechanical or electrical controls are provided, redundant and diverse controls shall be installed which will prevent the interconnecting valves from opening when the pressure in the high pressure system exceeds the Design Pressure of the lower pressure system.

(c) Means shall be provided such that operability of all components, controls, and interlocks can be verified by test.

(d) Means shall be provided to ensure that the leakage rate of the interconnecting valves does not exceed the relieving capacity of the relief devices on the lower pressure system.

(e) Adequate consideration shall be given to the control of fluid pressure caused by heating of the fluid trapped between two valves.

The low pressure system relieving capacity may be determined in accordance with NB-7311, on the basis of interconnecting valve being closed but leaking at a specified rate, when (3)(a) to (3)(e) above are met. The pressure relief devices or safety valves shall adjoin or be as close as possible to the interconnecting valve and shall relieve preferably to a system where the relieved effluent may be contained. The design of the overpressure protection system shall be based on pressure transients that are specified in the Design Specification, and all other applicable requirements of NB-7000 shall be met.

(b) When pressure-reducing valves are used and one or more pressure relief devices or safety valves are provided, bypass valves may be provided around the pressure-reducing valves. The combined relieving capacity of the pressure relief devices, safety valves, and relief piping shall be such that the lower pressure system service pressure will not exceed the lower

Page 137

pressure system Design Pressure by more than 10% if the pressure-reducing valve fails in the open position and the bypass valve is open at the same time. If the pressure-reducing valve and its bypass valve are mechanically or electrically interlocked so that only one may be open at any time the high pressure system is at a pressure higher than the Design Pressure of the low pressure system, then the relieving capacity of the pressure relief devices, safety valves, and relief piping shall be at least equal to the maximum capacity of the larger of the two valves. The interlocks shall be redundant and diverse.

(c) Exhaust and pump suction lines for any service and pressure shall have relief valves of a suitable size unless the lines and attached equipment are designed for the maximum pressure and temperature to which they may be accidentally or otherwise subjected.

(d) The effluent from relief devices may be discharged outside the containment only if provisions are made for the disposal of the effluent.

(e) Drip lines from steam headers, mains, separators, or other equipment operating at different pressures shall not discharge through the same trap. Where several traps discharge into a single header that is or may be under pressure, a stop valve and a check valve shall be provided in the discharge line from each trap. The Design Pressure of trap discharge piping shall not be less than the maximum discharge pressure to which it may be subjected. Trap discharge piping shall be designed for the same pressure as the trap inlet piping unless the discharge piping is vented to a system operated under lower pressure and has no intervening stop valves.

(f) Blowdown, dump, and drain piping from water spaces of a steam generation system shall be designed for saturated steam at the pressures and temperatures given below.

Vessel	Design	Design
Pressure,	Pressure,	Temperature,
psi	psi	°F

		410
601 to 900	400	450
901 to 1500	600	490
1501 and above	900	535

These requirements for blowdown, dump, and drain piping apply to the entire system beyond the blowdown valves to the blowdown tank or other points where the pressure is reduced to approximately atmospheric and cannot be increased by closing a valve. When pressures can be increased because of calculated pressure drop or otherwise, this shall be taken into account in the design. Such piping shall be designed for the maximum pressure to which it may be subjected.

(g) Pump discharge piping shall be designed for the maximum pressure exerted by the pump at any load and for the highest corresponding temperature actually existing.

(h) Where a fluid passes through heat exchangers in series, the design temperature of the piping in each section of the system shall conform to the most severe temperature condition expected to be produced by heat exchangers in that section.

NB-3613 Allowances

NB-3613.1 Corrosion or Erosion.

When corrosion or erosion is expected, the wall thickness of the piping shall be increased over that required by other design requirements. This allowance shall be consistent with the specified design life of the piping.

NB-3613.2 Threading and Grooving.

The calculated minimum thickness of piping that is to be threaded or grooved shall be increased by an allowance equal to the depth of the cut.

NB-3613.3 Mechanical Strength.

When necessary to prevent damage, collapse, or buckling of pipe due to superimposed loads from supports or other causes, the wall thickness of the pipe shall be increased, or, if this is impractical or would cause excessive local stresses, the superimposed loads or other causes shall be reduced or eliminated by other design methods.

NB-3620 DESIGN CONSIDERATIONS

NB-3621 Design and Service Loadings

The provisions of NB-3110 apply.

NB-3622 Dynamic Effects

NB-3622.1 Impact.

Impact forces caused by either external or internal loads shall be considered in the piping design.

NB-3622.2 Reversing Dynamic Loads.

Reversing dynamic loads (Fig. NB-3622-1) are those loads which cycle about a mean value and include building filtered loads, earthquake, and the reflected waves in a piping system due to flow transients resulting from sudden opening or closure of valves. A reversing dynamic load shall be treated as a nonreversing dynamic load in applying the rules of NB-3600 when either of the following conditions exist:

**(a) Nonreversing Dynamic Load
(Relief/Safety Valve Open End Discharge)**

**(b) Reversing Dynamic Load
(Earthquake Load Cycling About Normal Operating Condition)**

**(c) Nonreversing Followed By Reversing
(Initial Water Slug Followed By Reflected Pressure Pulses)**

FIG. NB-3622-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

FIG. NB-3622-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

(a) The frequency ratio of the dynamic dominant load driving frequency to the lowest piping system natural frequency

is less than 0.5.

(b) The number of reversing dynamic load cycles, exclusive of earthquake, exceeds 20.

NB-3622.3 Vibration.

Piping shall be arranged and supported so that vibration will be minimized. The designer shall be responsible, by design and by observation under startup or initial service conditions, for ensuring that vibration of piping systems is within acceptable levels.

NB-3622.4 Nonreversing Dynamic Loads.

Nonreversing dynamic loads (Fig. NB-3622-1) are those loads which do not cycle about a mean value and include the initial thrust force due to sudden opening or closure of valves and waterhammer resulting from entrapped water in two-phase flow systems.

NB-3623 Weight Effects

Piping systems shall be supported to provide for the effects of live and dead weights, as defined in the following subparagraphs, and they shall be arranged or properly restrained to prevent undue strains on equipment.

NB-3623.1 Live Weight.

The live weight shall consist of the weight of the fluid being handled or of the fluid used for testing or cleaning, whichever is greater.

NB-3623.2 Dead Weight.

The dead weight shall consist of the weight of the piping, insulation, and other loads permanently imposed upon the piping.

NB-3624 Thermal Expansion and Contraction Loads

NB-3624.1 Loadings, Displacements, and Restraints.

The design of piping systems shall take into account the forces and moments resulting from thermal expansion and contraction, equipment displacements and rotations, and the restraining effects of hangers, supports, and other localized loadings.

NB-3624.2 Analysis of Thermal Expansion and Contraction Effects.

The analysis of the effects of thermal expansion and contraction is covered in NB-3672.

NB-3624.3 Provision for Rapid Temperature Fluctuation Effects.

The Designer shall provide for unusual thermal expansion and contraction loads caused by rapid temperature fluctuations.

NB-3625 Stress Analysis

A stress analysis shall be prepared in sufficient detail to show that each of the stress limitations of NB-3640 and NB-3650 is satisfied when the piping is subjected to the loadings required to be considered by this Subarticle.

[98]

NB-3630 PIPING DESIGN AND ANALYSIS CRITERIA

(a) The design and analysis of piping when subjected to the individual or combined effects of the loadings defined in NB-3100 and NB-3620 may be performed in accordance with this Subarticle. Design for pressure loading shall be performed in accordance with the rules of NB-3640. Standard piping products that meet the requirements of ANSI B16.9 or NB-3649

satisfy the requirements of NB-3640, and only the analysis required by NB-3650 need be performed.

(b) Within a given piping system, the stress and fatigue analysis shall be performed in accordance with one of the methods given in NB-3650, NB-3200, or Appendix II. Stress indices are given in NB-3680 for standard piping products, for some fabricated joints, and for some fabricated piping products. Some piping products designed for pressure by applying the rules of NB-3649 may not be listed in NB-3680. For such products, the designer shall determine the stress indices as required in NB-3650.

(c) When a design does not satisfy the requirements of NB-3640 and NB-3650, the more detailed alternative analysis given in NB-3200 or the experimental stress analysis of Appendix II may be used to obtain stress values for comparison with the criteria of NB-3200.

(d) The requirements of this Subarticle shall apply to all Class 1 piping except as exempted under (1) or (2) below.

(1) Piping of 1 in. nominal pipe size or less which has been classified as Class 1 in the Design Specification may be designed in accordance with the design requirements of Subsection NC.

(2) Class 1 piping may be analyzed in accordance with the Class 2 analysis of piping systems in Subsection NC, using the allowable Class 2 stresses and stress limits, provided the specified service loads for which Level A and B Service Limits are designated meet all of the requirements stipulated in (a) through (e) below.

Page 140

(a) *Atmospheric to Service Pressure Cycle.* The specified number of times (including startup and shutdown) that the pressure will be cycled from atmospheric pressure to service pressure and back to atmospheric pressure during normal service does not exceed the number of cycles on the applicable fatigue curve of Figs. I-9.0 corresponding to an S_a value of three times the S_m value for the material at service temperature.

(b) *Normal Service Pressure Fluctuation.* The specified full range of pressure fluctuations during normal service does not exceed the quantity $\frac{1}{3} \times \text{Design Pressure} \times (S_a/S_m)$, where S_a is the value obtained from the applicable design fatigue curve for the total specified number of significant pressure fluctuations and S_m is the allowable stress intensity for the material at service temperature. If the total specified number of significant pressure fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_a value corresponding to the maximum number of cycles defined on the curve may be used. Significant pressure fluctuations are those for which the total excursion exceeds the quantity: $\text{Design Pressure} \times \frac{1}{3} \times (S/S_m)$, where S is defined as follows:

(1) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(2) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(c) *Temperature Difference - Startup and Shutdown.* The temperature difference, °F, between any two adjacent points²¹ of the component during normal service does not exceed $S_a/2E\alpha$, where S_a is the value obtained from the applicable design fatigue curves for the specified number of startup-shutdown cycles, α is the value of the instantaneous coefficient of thermal expansion and E is the modulus of elasticity at the mean value of the temperatures at the two points as given by Section II, Part D, Subpart 2, Tables TE and TM.

²¹Adjacent points are defined as points which are spaced less than the distance $2\sqrt{Rt}$ from each other, where R and t are the mean radius and thickness, respectively, of the vessel, nozzle, flange, or other component in which the points are located.

²⁶Normal service is defined as service, other than startup and shutdown, resulting in specified Service Loadings for which Level A Limits, Level B Limits, or Testing Limits are designated.

(d) *Temperature Difference - Normal Service.*⁹ The temperature difference, °F, between any two adjacent points²¹ does not change²² during normal service by more than the quantity $S_a/2E\alpha$, where S_a is the value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant temperature difference fluctuations. A temperature difference fluctuation shall be considered to be significant if its total algebraic range exceeds the quantity $S/2E\alpha$, where S is defined as follows:

(1) If the total specified number of service cycles is 10⁶ cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10⁶ cycles.

(2) If the total specified number of service cycles exceeds 10⁶ cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(e) *Temperature Difference - Dissimilar Materials.* For components fabricated from materials of differing moduli of elasticity or coefficients of thermal expansion, the total algebraic range of temperature fluctuation, °F, experienced by the component during normal service does not exceed the magnitude $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S_a is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature fluctuations, E_1 and E_2 are the moduli of elasticity, and α_1 and α_2 are the values of the instantaneous coefficients of thermal expansion (Section II, Part D, Subpart 2, Tables TE and TM) at the mean temperature value involved for the two materials of construction. A temperature fluctuation shall be considered to be significant if its total excursion exceeds the quantity $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S is defined as follows.

(1) If the total specified number of service cycles is 10⁶ cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10⁶ cycles.

(2) If the total specified number of service cycles exceeds 10⁶ cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve. If the two materials used have different applicable design fatigue curves, the lower value of S_a shall be used in applying the rules of this paragraph.

[98]

22 The algebraic range of the difference shall be used.

NB-3640 PRESSURE DESIGN

NB-3641 Straight Pipe

[98]

NB-3641.1 Straight Pipe Under Internal Pressure.

The minimum thickness of a pipe wall required for

Page 141

Design Pressure shall be determined from one of the following equations:

$$t_m = \frac{PD_o}{2(S_m + Py)} + A \quad (1)$$

$$t_m = \frac{Pd + 2A(S_m + Py)}{2(S_m + Py - P)} \quad (2)$$

(1 - 2)

(1 - 2)

where

A

= an additional thickness to provide for material removed in threading, corrosion or erosion allowance, and material required for structural strength of the pipe during erection, as appropriate, in.

D_o

= outside diameter of the pipe, in. (For design calculations, the specified outside diameter of pipe disregarding outside tolerances shall be used to obtain the value of t_m .)

d

= inside diameter, in.

P

= internal Design Pressure, psi

S_m

= maximum allowable stress intensity for the material at the Design Temperature taken from Section II, Part D, Subpart 1, Tables 2A and 2B, psi

t_m

= the minimum required wall thickness, in. [Eq. (2) is valid only if $d = D_o - 2t_m$. If pipe is ordered by its nominal wall thickness, the manufacturer's tolerance on wall thickness must be taken into account.]

y

= 0.4

The allowable working pressure of pipe may be determined from the following equation:

$$P_a = \frac{2S_m t}{D_o - 2yt} \quad (3)$$

(3)

where

P_a

= the calculated maximum allowable internal pressure for a straight pipe which shall at least equal the Design Pressure, psi. It may be used for piping products with pressure ratings equal to that of straight pipe (see ANSI B16.9). For standard flanged joints, the rated pressure shall be used instead of P_a . For other piping products where the pressure rating may be less than that of the pipe [for example, flanged joints designed to Appendix XI and reinforced branch connections (NB-3643), where part of the required reinforcement is in the run pipe], the Design Pressure of those products shall be used instead of P_a .

P_a may be rounded out to the next higher unit of 10.

t

= the specified or actual wall thickness minus, as appropriate, material removed in threading, corrosion or erosion allowance, material manufacturing tolerances, bending allowance (NB-3642.1), or material to be removed by counterboring, in.

[98]

**TABLE NB-3642.1(b)-1
BEND RADIUS VERSUS THICKNESS**

Radius of Bends	Minimum Thickness Recommended Prior to Bending [Note (1)]
6 pipe diameters or greater	$1.06t_m$
5 pipe diameters	$1.08t_m$
4 pipe diameters	$1.16t_m$
3 pipe diameters	$1.25t_m$

NOTE:

(1) t_m is determined by Eq. (1) or (2) of NB-3641.1.

TABLE NB-3642.1(b)-1 BEND RADIUS VERSUS THICKNESS

NB-3641.2 Straight Pipe Under External Pressure.

The rules of NB-3133 shall be used.

NB-3642 Curved Segments of Pipe

NB-3642.1 Pipe Bends.

The wall thickness for pipe bends shall be determined in the same manner as determined for straight pipe in accordance with NB-3641, subject to the limitations given in (a), (b), and (c) below.

- (a) The wall thickness after bending shall not be less than the minimum wall thickness required for straight pipe.
- (b) The information in Table NB-3642.1(b)-1 is given to guide the designer when ordering pipe.
- (c) For the effects of ovality on stress levels, see NB-3680.

NB-3642.2 Elbows.

Elbows, manufactured in accordance with the standards listed in Table NB-3132-1 as limited by NB-3612.1, shall be considered as meeting the requirements of NB-3640, except that the minimum thickness in the crotch region of short radius welding elbows in accordance with ANSI B16.28 shall be 20% greater than the minimum thickness required for the straight pipe by Eq. (1) (NB-3641.1). The crotch region is defined as that portion of the elbow between $\phi = 210$ deg. and 330 deg., where ϕ is defined in Fig. NB-3685.2-1.

Page 142

NB-3643 Intersections

NB-3643.1 General Requirements

- (a) The rules contained in this paragraph meet the requirements of NB-3640 in the vicinity of branch connections.
- (b) Openings shall be circular, elliptical, or of any other shape that results from the intersection of a circular or elliptical cylinder with a cylindrical shape. Additional restrictions affecting stress indices are given in NB-3680.
- (c) Openings are not limited in size except to the extent provided for in connection with the stress indices listed in NB-3680.
- (d) All references to dimensions apply to the finished dimensions, excluding material added for corrosion allowance.
- (e) Any type of opening permitted in these rules may be located in a welded joint.
- (f) Where intersecting pipes are joined by welding a branch to a run pipe as shown in Fig. NB-3643.3(a)-2, the angle α between axes of the intersecting pipes shall not be less than 60 deg. or more than 120 deg. For angles outside this range, use fittings as specified in NB-3643.2(a) or (b).

NB-3643.2 Branch Connections.

Branch connections in piping may be made by using one of the products or methods set forth in (a) through (c) below.

- (a) Flanged, butt welding, or socket welding fittings meeting the applicable ANSI standards listed in Table NB-3132-1, subject to the limitations or requirements of this Subsection, are acceptable. Fittings that comply with the test requirements of ANSI B16.9 or of NB-3649 are not required to meet requirements for reinforcement given in NB-3643.3.
- (b) Welded outlet fittings, cast or forged branches, pipe adapters, couplings, or similar products with butt welding, socket welding, or flanged ends are acceptable for attachment to the run pipe when limited to types that have integral reinforcement and are attached to the main run by welding [Figs. NB-4244(a)-1 and NB-4244(b)-1].
- (c) An extruded outlet at right angles to the run pipe is acceptable.

NB-3643.3 Reinforcement for Openings

(a) Nomenclature

(1) The following terms are as shown in Fig. NB-3643.3(a)-1.

d_o	= outside diameter of the branch pipe, in.
R_m	= mean radius of the run pipe, in.
r_i	= inside radius of branch pipe, in.
r_m	= mean radius of the branch pipe, in.
	= $r_i + 0.5T_b$
r'_m	= mean radius of the branch pipe, in.

	$= r_i + 0.5T_b$
r_n	= nominal radius [sketch (c) only], in.
	$= r_i + 0.5T_b + 0.5y \cos \theta$
r_2	= transition radius between branch or extruded lip and run pipe, in.
T_b	= nominal thickness of the reinforced branch, not including corrosion allowance or mill tolerance, in.
T_b	= nominal thickness of the branch pipe, not including corrosion allowance or mill tolerance, in.
T_o	= corroded finished thickness or extruded outlet measured at a height of r_2 above the outside surface of the run pipe, in.
T_r	= nominal thickness of the run pipe, not including corrosion allowance or mill tolerance, in.
y	= slope offset distance, in.
θ	= angle between vertical and slope, deg.

(2) The following terms are as shown on Fig. NB-3643.3(a)-2.

A_1	= metal area available for reinforcement, sq in.
A_2	= metal area available for reinforcement, sq in.
A_3	= metal area available for reinforcement, sq in.
d	= diameter in the given plane of the finished opening in its corroded condition, in.
L_A	= half-width of reinforcement zone measured along the midsurface of the run pipe, in.
L'_A	= half-width of zone in which two-thirds of compensation must be placed, in.
L_N	= limit of reinforcement measured normal to run pipe wall, in.
r	= radius of the finished opening in the corroded condition, in.
T_r	= nominal thickness of the run pipe, not including corrosion allowance or mill tolerance, in.
t_b	= minimum required thickness of the branch pipe, not including corrosion allowance, according to NB-3641.1, in.
	$= t_m - A$
t_r	= minimum required thickness of the run pipe, not including corrosion allowance, according to NB-3641.1, in.
	$= t_m - A$
α	= angle between axes of branch and run (90 deg. $\geq \alpha \geq$ 60 deg.), deg.

(3) The following terms are as shown in Fig. NB-3643.3(a)-3.

D

D_o

= outside diameter of the run pipe, in.

T_o

= finished thickness of the extruded outlet in the corroded condition measured at a height equal to r_2 above the outside surface of the main run, in.

T_r

= minimum thickness of the run pipe after extrusion of the opening, not including corrosion allowance or mill tolerance, in. Allowance shall be made for thinning of the run pipe wall by the extrusion of the opening, if it occurs.

h

= height of the extruded lip, equal to or greater than r_2 , in.

GENERAL NOTE:

If L_1 equals or exceeds $0.5 \sqrt{r_i T_b}$, then r'_m can be taken as the radius to the center of T_b .

FIG. NB-3643.3(a)-1 BRANCH CONNECTION NOMENCLATURE

FIG. NB-3643.3(a)-1 BRANCH CONNECTION NOMENCLATURE

FIG. NB-3643.3(a)-2 TYPICAL REINFORCEMENT OF OPENINGS

FIG. NB-3643.3(a)-2 TYPICAL REINFORCEMENT OF OPENINGS

(b) Requirements

(1) Reinforcement shall be provided in amount and distribution so that the requirements for the area of reinforcement are satisfied for all planes through the center of the opening and normal to the surface of the run pipe, except that openings need not be provided with reinforcement if all of the requirements of (a), (b), and (c) below are met.

(a) A single opening has a diameter not exceeding $0.2\sqrt{R_m - T_r}$ or, if there are two or more openings within any circle of diameter, $2.5\sqrt{R_m - T_r}$ but the sum of the diameters of such unreinforced openings shall not exceed $0.25\sqrt{R_m - T_r}$.

(b) No two unreinforced openings shall have their centers closer to each other, measured on the inside wall of the run pipe, than the sum of their diameters.

(c) No unreinforced opening shall have its center closer than $2.5\sqrt{R_m - T_r}$ to the edge of any other locally stressed area.

GENERAL NOTE:
The areas A_1 , A_2 , and A_3 , shown are only one-half of those defined in NB-3643.3(f)(3).

FIG. NB-3643.3(a)-3 TYPICAL REINFORCED EXTRUDED OUTLET

FIG. NB-3643.3(a)-3 TYPICAL REINFORCED EXTRUDED OUTLET

(2) The total cross-sectional area of reinforcement A required in any given plane for a pipe under internal pressure shall not be less than:

$$A = dt_r(2 - \sin \alpha)$$

(3) The required reinforcing material shall be uniformly distributed around the periphery of the branch except that, in the case of branches not at right angles, the designer may elect to provide additional reinforcement in the area of the crotch.

(c) *Limits of Reinforcement.* The boundaries of the cross-sectional area in any plane passing through the axis of the opening within which metal may be located to have value as reinforcement are designated as the limits of reinforcement for that plane, and they are given in (1) and (2) below.

(1) The limits of reinforcement, measured along the midsurface of the nominal wall thickness of the run pipe, L_A , shall be at a distance on each side of the axis of the opening that is equal to the greater of (a) or (b) below:

(a) the diameter of the finished opening in the corroded condition; or

(b) the radius of the finished opening in the corroded condition r , plus the nominal thickness of the run pipe T_r , plus the nominal thickness of the branch wall T_b

(c) In addition, two-thirds of the required reinforcement shall be provided within the greater of the limit given in (b) above and the limit L'_A which is the greater of either

$$r + 0.5 \sqrt{R_m - T_r}$$

or

$$r + T_b/\sin \alpha + T_r$$

(2) The limits of reinforcement measured normal to the wall of the run pipe L_N shall conform to the contour of the surface of the branch at a distance from each surface equal to the limits given in (a) and (b) below and as shown in Fig. NB-3643.3(a)-1.

(a) For nozzle types of Fig. NB-3643.3(a)-1 sketches (a), (b), and (d):

$$L_N = 0.5 \sqrt{r_m - T_b} + 0.5r_2$$

(b) For Fig. NB-3643.3(a)-1 sketch (c):

$$L_N = 0.5 \sqrt{r_n - T_b}$$

(d) *Metal Available for Reinforcement*

(1) Metal may be counted as contributing to the area of reinforcement called for in NB-3643.3(b) if it lies within the area of reinforcement specified in NB-3643.3 (c), and it shall be limited to material that meets the requirements of (a), (b), and (c) below:

(a) metal forming a part of the run wall that is in excess of that required on the basis of NB-3641.1 and is exclusive of corrosion allowance shown in Fig. NB-3643.3(a)-2;

(b) similar excess metal in the branch wall, if the branch is integral with the run wall or is joined to it by a full penetration weld, as denoted by A_1 in Fig. NB-3643.3(a)-2;

(c) weld metal that is fully continuous with the wall of the run pipe, as denoted by area A_2 in Fig. NB-3643.3(a)-2.

(2) The mean coefficient of thermal expansion of the metal to be included as reinforcement under (1)(b) and (1)(c) above shall be within 15% of the value for the metal in the wall of the run pipe.

(3) Metal available for reinforcement shall not be considered as applying to more than one opening.

(4) Metal not fully continuous with the run pipe, as that in branches attached by partial penetration welds, shall not be counted as reinforcement.

(e) *Strength of Metal.* Material used for reinforcement shall preferably be the same as that of the wall of the run pipe. If material with a lower design stress intensity S_m is used, the area provided by such material shall not be counted at full value but shall be multiplied by the ratio (less than unity) of the design stress intensity values S of the reinforcement

material and of the run pipe material before being counted as reinforcement. No reduction in the ^mreinforcement requirement may be taken for the increased strength of either the branch material or weld metal having a higher design stress intensity value than that of the material of the run pipe wall. The strength of the material at the point under consideration shall be used in the fatigue analysis.

(f) *Requirements for Extruded Outlets.* Extruded outlets shall meet all of the requirements of NB-3643.3(a) and NB-3643.3(b), and these rules apply only where the axis of the outlet intersects and is perpendicular to the axis of the run pipe.

(1) *Geometric Requirements*

(a) An extruded outlet is one in which the extruded lip at the outlet has a height h above the surface of the run pipe that is equal to or greater than

Page 147

the transition radius between the extruded lip and the run pipe r_2 .

(b) The minimum value of the transition radius r_2 shall not be less than $0.05d_o$, except that on branch pipe sizes larger than 30 in. (750 mm) the transition radius need not exceed 1.5 in. (38 mm). The maximum value of the transition radius r_2 shall be limited as follows: for branch pipes nominally 8 in. (DN 200) and larger, the dimension of the transition radius shall not exceed $0.10d_o + 0.50$ in. (13 mm); for branch pipe sizes nominally less than 8 in. (DN 200), r_2 shall not be greater than 1.25 in. (31 mm).

(c) When the external contour contains more than one radius, the radius of any arc sector of approximately 45 deg. shall meet the requirements given in (b) above.

(d) Machining shall not be employed to meet the requirements of (b) and (c) above.

(2) *Limits of Reinforcement*

(a) The height of the reinforcement zone shall be limited as shown in Fig. NB-3643.3(a)-3:

$$L_N = 0.5 \sqrt{d_o T_o}$$

(b) The half width of the reinforcement zone shall be limited as shown in Fig. NB-3643.3(a)-3:

$$L_A = d$$

(3) *Metal Available for Reinforcement.* The reinforcement area shall be the sum of areas $A_1 + A_2 + A_3$ defined in (a), (b), and (c) below and shown in Fig. NB-3643.3(a)-3. Metal counted as reinforcement shall not be applied to more than one opening.

(a) Area A_1 is the area lying within the reinforcement zone that results from any excess thickness available in the wall of the branch pipe:

$$A_1 = 2L_N(T_b - t_b)$$

(b) Area A_2 is the area lying within the reinforcement zone that results from excess thickness available in the lip of the extruded outlet:

$$A_2 = 2r_2(T_o - T_b)$$

(c) Area A_3 is the area lying within the reinforcement zone that results from any excess thickness in the run pipe wall:

$$A_3 = d(T_r - t_r)$$

FIG. NB-3644(b)-1 MITER JOINT GEOMETRY

FIG. NB-3644(b)-1 MITER JOINT GEOMETRY

NB-3644 Miters

Mitered joints may be used in piping systems under the conditions stipulated in (a) through (d) below.

(a) The minimum thickness of a segment of a miter shall be determined in accordance with NB-3641. The minimum thickness thus determined does not allow for the discontinuity stresses that exist at the junction between segments. The discontinuity stresses are reduced for a given miter as the number of segments is increased.

(b) The angle θ in Fig. NB-3644(b)-1 shall not be more than $22\frac{1}{2}$ deg.

(c) The center line distance S between adjacent miters shall be in accordance with Fig. NB-3644(b)-1.

(d) Stress indices and flexibility factors shall be determined in accordance with the requirements of NB-3681(d).

NB-3646 Closures

(a) Closures in piping systems may be made by use of closure fittings, such as blind flanges or threaded or welded plugs or caps, either manufactured in accordance with standards listed in Table NB-3132-1 and used within the specified pressure-temperature ratings, or made in accordance with (b) below.

(b) Closures not manufactured in accordance with the standards listed in Table NB-3132-1 may be made in accordance with the rules for Class 2 vessels using the equation:

$$t_m = t + A$$

where

where

t	= pressure design thickness, in., calculated for the given closure shape and direction of
-----	---

Page 148

loading using appropriate equations and procedures for Class 2 Vessels, except that the symbols used to determine t shall be defined as:

A	= sum of mechanical allowances (NB-3613), in.
-----	---

P	= Design Pressure, psi
-----	------------------------

S	= applicable design stress intensity value S_m from Section II, Part D, Subpart 1, Tables 2A and 2B, psi
-----	--

t_m	= minimum required thickness, in.
-------	-----------------------------------

(c) Connections to closures may be made by welding or extruding. Connections to the closure shall be in accordance with the limitations provided for such connections in NB-3643 and Figs. NB-4243-1, NB-4244(a)-1, NB-4244(b)-1, and NB-4244(c)-1 for branch connections. If the size of the opening is greater than one-half the inside diameter of the closure, the opening should be considered as a reducer in accordance with NB-3648.

(d) Openings in closures may be reinforced in accordance with the requirements of NB-3643.

(e) Flat heads that have an opening with a diameter that does not exceed one-half of the head diameter shall have a total cross-sectional area of reinforcement not less than $dt/2$, where

d	= the diameter of the finished opening, in.
-----	---

t	= the design thickness for the closure, in.
-----	---

NB-3647 Pressure Design of Flanged Joints and Blanks

NB-3647.1 Flanged Joints

(a) Flanged joints manufactured in accordance with the standards listed in Table NB-3132-1, as limited by NB-3612.1, shall be considered as meeting the requirements of NB-3640.

(b) Flanged joints not included in Table NB-3132-1 shall be designed in accordance with XI-3000, including the use of the appropriate allowable stress given in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3.

NB-3647.2 Permanent Blanks.

The minimum required thickness of permanent blanks (Fig. NB-3647.2-1) shall be calculated from the following equations:

$$t_m = t + A \quad (7)$$

(7)

where

A

= sum of the mechanical allowances, in. (NB-3613)

t

= pressure design thickness, in., calculated from Eq. (8)

t_m

= minimum required thickness, in.

$$t = d_6 \left(\frac{3P}{16S_m} \right)^{1/2} \quad (8)$$

(8)

where

d_6

= inside diameter of the gasket for raised or flat face flanges or the pitch diameter of the gasket for retained gasketed flanges, in.

P

= Design Pressure, psi

S_m

= the design stress intensity value in accordance with Section II, Part D, Subpart 1, Tables 2A and 2B, psi

[98]

NB-3647.3 Temporary Blanks.

Blanks to be used for test purposes only shall have a minimum thickness not less than the Design Pressure thickness t , calculated from Eq. (8) above, except that P shall not be less than the test pressure and the design stress intensity value S_m may be taken as 95% of the specified minimum yield strength of the blank material (Section II, Part D, Subpart 1, Table Y-1).

[98]

NB-3648 Reducers

Reducer fittings manufactured in accordance with the standards listed in Table NB-3132-1 shall be considered suitable for use. Where butt welding reducers are made to a nominal pipe thickness, the reducers shall be considered suitable for use with pipe of the same nominal thickness.

NB-3649 Pressure Design of Other Piping Products

Other piping products manufactured in accordance with the standards listed in Table NB-3132-1 shall be considered suitable for use provided the design is consistent with the design philosophy of this Subsection. Piping products not included in Table NB-3132-1 may be used if they satisfy the requirements of NB-3200. The pressure design shall be based on an analysis consistent with this Subsection, or experimental stress analysis as described in Appendix II, or an ANSI B16.9 type burst test. The bursting pressure in a B16.9 type burst test shall be equal to or greater than that of the weakest pipe to be attached to the piping product, where the burst pressure of the weakest pipe is calculated by the equation:

$$P = 2St/D_o$$

FIG. NB-3647.2-1 TYPES OF PERMANENT BLANKS

FIG. NB-3647.2-1 TYPES OF PERMANENT BLANKS

where

D_o	= outside diameter of pipe, in.
S	= specified minimum tensile strength of pipe material, psi
t	= minimum specified wall thickness of pipe, in.

NB-3649.1 Expansion Joints.

Rules are currently under development for the application of expansion joints in piping systems. Until these rules are available, expansion joints shall not be used in piping.

NB-3650 ANALYSIS OF PIPING PRODUCTS

NB-3651 General Requirements

NB-3651.1 Piping Products for Which Stress Indices Are Given.

Piping products, for which values of stress indices B , C , and K are given in NB-3683.2 and which meet the requirements of NB-3640, satisfy the design criteria of NB-3611 provided they comply with these rules. To validate a design in accordance with these rules, it is necessary to perform several flexibility analyses in accordance with the requirements of NB-3672 and to use the moments and forces obtained from these analyses as required in NB-3650.

NB-3651.2 Piping Products for Which Stress Indices Are Not Available.

For analysis of flanged joints, see NB-3658. For other piping products for which stress indices are not available, see NB-3680.

NB-3651.3 Attachments

(a) Lugs, brackets, stiffeners, and other attachments may be welded, bolted, and studded to, or bear upon the outside or inside of piping. The interaction effects of attachments on the pressure boundary, producing thermal gradients, localized bending stresses, stress concentrations, or restraint of the pressure boundary

Page 150

shall be considered by the piping designer. Standard clamps generally have a negligible effect on the pressure boundary. However, the effects of clamps on thin-wall piping may need to be evaluated.

(b) Attachments shall meet the requirements of NB-3135.

(c) Figure NB-4433-1 shows some typical types of attachment welds (NB-4430).

NB-3652 Consideration of Design Conditions

The primary stress intensity limit is satisfied if the requirement of Eq. (9) is met:

$$B_1 \frac{PD_o}{2t} + B_2 \frac{D_o}{2I} M_i \leq 1.5 S_m \quad (9)^{23}$$

(9)²³

where

B_1, B_2

= primary stress indices for the specific product under investigation (NB-3680)

D_o

= outside diameter of pipe, in. (NB-3683)

I

= moment of inertia, in.⁴ (NB-3683)

M_i

= resultant moment due to a combination of Design Mechanical Loads, in.-lb. All Design Mechanical Loads, and combinations thereof shall be provided in the Design Specification. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment (i.e., resultant moments from different load sets shall not be used in calculating the moment M_i). If the method of analysis for earthquake or other dynamic loads is such that only magnitudes without relative algebraic signs are obtained, the most conservative combination shall be assumed.

P

= Design Pressure, psi

S_m

= allowable design stress intensity value, psi (Section II, Part D, Subpart 1, Tables 2A and 2B)

t

= nominal wall thickness of product, in. (NB-3683)

²³ For piping products, such as tees and branch connections, the second term of Eqs. (9), (10), and (11), namely that containing M_i is to be calculated as referred to in NB-3683.1(d).

NB-3653 Consideration of Level A Service Limits

All load sets, for which Level A Service Limits are to be evaluated, shall satisfy the fatigue requirements of NB-3653.1 through NB-3653.6 and the thermal stress ratchet requirement of NB-3653.7.

NB-3653.1 Satisfaction of Primary Plus Secondary Stress Intensity Range

(a) This calculation is based upon the effect of changes which occur in mechanical or thermal loadings which take place as the system goes from one load set, such as pressure, temperature, moment, and force loading, to any other load set which follows it in time. It is the range of pressure, temperature, and moment between two load sets which is to be used in the calculations. For example, one of the load sets to be included is that corresponding to zero pressure, zero moment, and room temperature. Equation (10) shall be satisfied for all pairs of load sets:

$$S_n = C_1 \frac{P_o D_o}{2t} + C_2 \frac{D_o}{2I} M_i + C_3 E_{ab}$$

$$\times | \alpha_a T_a - \alpha_b T_b | \leq 3S_m \quad (10)$$

(10)

(b) If for one or more pairs of load sets Eq. (10) is not met, the piping product may still be satisfactory, provided that the conditions of NB-3653.6 are met or provided that the requirements of NB-3200 are satisfied.

(c) The nomenclature used in Eq. (10) is defined as follows:

C_1, C_2, C_3	= secondary stress indices for the specific component under investigation (NB-3680)
D_o, t, I, S_m	= as defined for Eq. (9)
$d_a(d_b)$	= inside diameter on side $a(b)$ of a gross structural discontinuity or material discontinuity, in.
E_{ab}	= average modulus of elasticity of the two sides of a gross structural discontinuity or material discontinuity at room temperature, psi (Section II, Part D, Subpart 2, Tables TM)
M_i	= resultant range of moment which occurs when the system goes from one service load set to another, in.-lb. Service loads and combinations thereof shall be provided in the Design Specification. In the combination of moments from load sets, all directional moment components in the same direction shall be combined before determining the resultant moment (i.e., resultant moments from different load sets shall not be used in calculating the moment range M_i). Weight effects need not be considered in determining the

Page 151

loading range since they are noncyclic in character. If the method of analysis is such that only magnitudes without relative algebraic signs are obtained, the most conservative combination shall be assumed. If a combination includes reversing dynamic loads, M_i shall be either: (1) the resultant range of moment due to the combination of all loads considering one-half the range of the reversing dynamic loads; or (2) the resultant range of moment due to the full range of the reversing dynamic loads alone, which ever is greater.

P_o = range of service pressure, psi

$T(T)$ = range of average temperature on side $a(b)$ of gross structural

$t_a(t_b)$

$\alpha_a(\alpha_b)$

discontinuity or material discontinuity, °F. For generally cylindrical shapes, the averaging of T (NB-3653.2) shall be over a distance of $\sqrt{d_a t_a}$ for T_a and over a distance of $\sqrt{d_b t_b}$ for T_b .

= average wall thickness through the length $\sqrt{d_a t_a}$ ($\sqrt{d_b t_b}$), in. A trial and error solution for t_a and t_b may be necessary.

= coefficient of thermal expansion on side $a(b)$ of a gross structural discontinuity or material discontinuity, at room temperature, 1/°F (Section II, Part D, Subpart 2, Tables TE)

NB-3653.2 Satisfaction of Peak Stress Intensity Range

(a) For every pair of load sets (NB-3653), calculate S_p values using Eq. (11):

$$S_p = K_1 C_1 \frac{P_o D_o}{2t} + K_2 C_2 \frac{D_o}{2I} M_i + \frac{1}{2(1 - \nu)} K_3 E \alpha |\Delta T_1| + K_3 C_3 E_{ab} \times |\alpha_a T_a - \alpha_b T_b| + \frac{1}{1 - \nu} E \alpha |\Delta T_2| \quad (11)$$

(11)

NOTE: This simplified analysis is intended to provide a value of S_p that conservatively estimates the sum of $P_L + P_b + P_e + Q + F$ as required in Fig. NB-3222-1.

The nomenclature used in Eq. (11) is defined as follows:

$E\alpha$

= modulus of elasticity (E) times the mean coefficient of thermal expansion (α) both at room temperature, psi/°F

K_1, K_2, K_3

= local stress indices for the specific component under investigation (NB-3680)

$|\Delta T_2|$

= absolute value of the range for that portion of the nonlinear thermal gradient through the wall thickness not included in ΔT_1 as shown below, °F

$|\Delta T_1|$

= absolute value of the range of the temperature difference

between the temperature of the outside surface T_o and the temperature of the inside surface T_i of the piping product assuming moment generating equivalent linear temperature distribution, °F

For a quantitative definition of $|\Delta T_1|$ and $|\Delta T_2|$, see NB-3653.2(b) below. All other terms are as defined for Eq. (10).

(b) *Quantitative Definitions of $|\Delta T_1|$ and $|\Delta T_2|$.*

The following nomenclature is used:

T_i	= value of $T(y)$ at inside surface, °F = $T(-t/2)$
T_o	= value of $T(y)$ at outside surface, °F = $T(t/2)$
$T_j(y), T_k(y)$	= temperature, as a function of radial position, for load set j and load set k , respectively, °F
$T(y)$	= temperature distribution range from condition j to condition k , °F = $T_k(y) - T_j(y)$
t	= thickness of the wall of the pipe or element, in.
y	= radial position in the wall, measured positive outward from the midthickness position ($-t/2 \leq y \leq t/2$), in.

Then the temperature distribution range $T(y)$ may be thought of as being composed of three parts:

(1) a constant value:

$$T = (1/t) \int_{-t/2}^{t/2} T(y) dy$$

which is the average value through the thickness. T may be used in determining free thermal expansions. Also, the values of T determined (for the same pair of load sets) or two locations a and b on either side of a gross discontinuity may be used for T_a and T_b in Eqs. (10) and (11).

(2) a linear portion, with zero average value, having variation given by:

FIG. NB-3653.2(b)-1 DECOMPOSITION OF TEMPERATURE DISTRIBUTION RANGE

FIG. NB-3653.2(b)-1 DECOMPOSITION OF TEMPERATURE DISTRIBUTION RANGE

$$V = (12/t^2) \int_{-t/2}^{t/2} yT(y)dy$$

(3) a nonlinear portion with a zero average value and a zero first moment with respect to the mid-thickness. This decomposition of $T(y)$ into three parts is illustrated in Fig. NB-3653.2(b)-1. The value of ΔT_1 to be used in Eq. (11) is the variation V of the linear portion:

$$\Delta T_1 = V$$

The value of ΔT_2 to be used in Eq. (11) is as follows:

$$\Delta T_2 = \max. (|T_o - T_i - \frac{1}{2}V|, |T_i - T_o - \frac{1}{2}V|, 0)$$

NB-3653.3 Alternating Stress Intensity.

The alternating stress intensity S_{alt} is equal to one-half the value of S_p ($S_{alt} = S_p/2$) calculated in Eq. (11) above.

NB-3653.4 Use of Design Fatigue Curve.

Enter the applicable design fatigue curve, Figs. I-9.0, on the ordinate using $S_a = S_{alt}$ and find the corresponding number of cycles on the abscissa. If the service cycle being considered is the only one that produces significant fluctuating stresses, this is the allowable number of cycles.

NB-3653.5 Cumulative Damage.

The cumulative damage shall be evaluated in accordance with NB-3222.4(e)(5). If N_i is greater than the maximum number of cycles defined on the applicable design fatigue curve, the value of n_i/N_i may be taken as zero.

NB-3653.6 Simplified Elastic-Plastic Discontinuity Analysis.

If Eq. (10) cannot be satisfied for all pairs of load sets, the alternative analysis described below may still permit qualifying the component under NB-3650. Only those pairs of load sets which do not satisfy Eq. (10) need be considered.

(a) Equation (12) shall be met:

$$S_e = C_2 \frac{D_o}{2I} M_i^* \leq 3S_m \quad (12)$$

(12)

where

M_i^*

= same as M_i in Eq. (10), except that it includes only moments due to thermal expansion and thermal anchor movements, in.-lb

S_e

= nominal value of expansion stress, psi

(b) The primary plus secondary membrane plus bending stress intensity, excluding thermal bending and thermal expansion stresses, shall be $< 3S_m$. This requirement is satisfied by meeting Eq. (13) below:

$$C_1 \frac{P_o D_o}{2t} + C_2 \frac{D_o M_i}{2I} + C'_3 E_{ab} \times |\alpha_a T_a - \alpha_b T_b| \leq 3S_m \quad (13)$$

(13)

where

C_3

= values in Table NB-3681(a)-1

M_i

= as defined in NB-3652 and all other variables are as defined in NB-3653

(c) If these conditions are met, the value of S_{alt} shall be calculated by Eq. (14):

$$S_{alt} = K_e \frac{S_p}{2} \quad (14)$$

(14)

where

K_e

= 1.0 for $S_n \leq 3S_m$

= $1.0 + [(1 - n)/n(m - 1)](S_n/3S_m - 1)$, for $3S_m < S_n < 3mS_m$

= $1/n$, for $S_n \geq 3mS_m$

Page 153

m, n

= material parameters given in Table NB-3228.5(b)-1

S_{alt}

= alternating stress intensity, psi

S_n

= primary plus secondary stress intensity value calculated in Eq. (10), NB-3653.1, psi

S_p

= peak stress intensity value calculated by Eq. (11), (NB-3653.2), psi

S_{alt} for all load sets shall be calculated in accordance with NB-3653.3 or Eq. (14). Using the alternating stress intensity values calculated by the above procedures, determine the cumulative usage factor in accordance with NB-3653.4 and NB-3653.5. The cumulative usage factor shall not exceed 1.0.

NB-3653.7 Thermal Stress Ratchet.

For all pairs of load sets, the value of the range of ΔT_1 cannot exceed that calculated as follows:

$$\Delta T_1 \text{ range} \leq \frac{y' S_y}{0.7 E \alpha} C_4$$

where

C_4

= 1.1 for ferritic material

= 1.3 for austenitic material

$E\alpha$

= as defined for Eq. (11), psi/°F

P

= maximum pressure for the set of conditions under consideration, psi

S_y

= yield strength value, psi, taken at average fluid temperature of the transient under consideration

x

= $(PD_o/2t) (1/S_y)$

y'

= 3.33, 2.00, 1.20, and 0.80 for $x = 0.3, 0.5, 0.7$, and 0.8 , respectively

NB-3654 Consideration of Level B Service Limits

The procedures for analyzing Service Loadings for which Level B Service Limits are designated, are the same as those given in NB-3653 for Level A Service Limits. All load sets, including Level A and Level B Service Loadings, shall satisfy the fatigue requirements of NB-3653.1 through NB-3653.6 and the thermal stress ratchet requirement of NB-3653.7.

NB-3654.1 Permissible Pressure.

For Level B Service Limits [NCA-2142.4(b)(2)], the permissible pressure shall not exceed the pressure P_a calculated in accordance with Eq. (3) of NB-3641.1, by more than 10%.

NB-3654.2 Analysis of Piping Components.

For Service Loadings for which Level B Service Limits are designated, the requirements of (a) or (b) below shall apply.

(a) For Service Loadings for which Level B Service Limits are designated which do not include reversing dynamic loads (NB-3622.2) or have reversing dynamic loads combined with nonreversing dynamic loads (NB-3622.4), the

conditions of Eq. (9) shall be met using Service Level B coincident pressure P and moments M_i which result in the maximum calculated stress. The allowable stress to be used for this condition is $1.8S_m$, but not greater than $1.5S_y$.

S_y

= yield strength value, psi, taken at average fluid temperature of the transient under consideration

(b) For Service Loadings for which Level B Service Limits are designated which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of NB-3653 for Level A Service Limits shall be met. In addition, any deflection limits prescribed by the Design Specification must be satisfied.

NB-3655 Consideration of Level C Service Limits

NB-3655.1 Permissible Pressure.

When Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are specified, the permissible pressure shall not exceed the pressure P_a calculated in accordance with Eq. (3) of NB-3641.1, by more than 50%.

NB-3655.2 Analysis of Piping Components.

For Service Loadings for which Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are designated, the requirements of (a) or (b) below shall apply.

(a) For Service Loadings for which Level C Service Limits are designated which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the conditions of Eq. (9) of NB-3652 shall be met using Service Level C coincident pressure P and moments M_i which result in the maximum calculated stress. The allowable stress to be used for this condition is $2.25S_m$ but not greater than $1.8S_y$.

(b) For Service Loadings for which Level C Service Limits are designated which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of NB-3656(b) shall be satisfied using the allowable stress in NB-3656(b)(2), 70% of the allowable stress in NB-3656(b)(3), and 70% of the allowable loads in NB-3656(b)(4).

NB-3655.3 Deformation Limits.

Any deformation or deflection limits prescribed by the Design Specifications

Page 154

shall be considered with respect to Level C Service Limits.

NB-3656 Consideration of Level D Service Limits

If the Design Specifications specify any Service Loading for which Level D Limits are designated [NCA-2142.2(b)(4)], the requirements of (a), (b), or (c) below shall apply.

(a) For Service Loadings for which Level D Service Limits are designated which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the requirements of (1) and (2) below shall apply.

(1) The permissible pressure shall not exceed 2.0 times the pressure P_a calculated in accordance with Eq. (3) of NB-3641.1.

(2) The conditions of Eq. (9) of NB-3652 shall be met. The allowable stress to be used for this condition is $3.0S_m$, but not greater than $2.0S_y$.

(b) For piping fabricated from material designated P-No. 1 through P-No. 9 in Table 2A, Section II, Part D and limited to $D/t \leq 50$ if Level D Service Limits are designated which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of (1) through (5) below shall apply.

(1) The pressure occurring coincident with the earthquake or other reversing type loading shall not exceed the Design

Pressure.

(2) The sustained stress due to weight loading shall not exceed the following:

$$B_2 \frac{D_o}{2I} M_W \leq 0.5 S_m$$

where

M_W

= resultant moment due to weight effects (NB-3623)

(3) The stress due to weight and inertial loading due to reversing dynamic loads in combination with the Level D coincident pressure shall not exceed the following:

$$B_1 \frac{P_D D_o}{2I} + B_2 \frac{D_o}{2I} M_E \leq 4.5 S_m$$

where

M_E

= the amplitude of the resultant moment due to the inertial loading from the earthquake, other reversing type dynamic events and weight. Earthquake and other reversing dynamic loads shall be computed from a linear elastic response

spectrum analysis as defined in Appendix N-1226, except the spectrum peak broadening value Δf_g in N-1226.3 shall not be less than 15% and, in place of the damping values for both large and small diameter piping systems in Table N-1230-1 for Operating Basis Earthquake and Safe Shutdown Earthquake, a value of 5 shall be used. The ground motion design input for generating the floor response spectrum to be used in the linear elastic analysis shall meet the requirements of Appendix N-1211(a) and N-1211(b). Moments and forces may be computed using a methodology other than prescribed above if the alternate methodology is demonstrated to produce results which envelope the prescribed methodology results. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment. If the method of analysis is such that only magnitude without algebraic signs is obtained, the most conservative combination shall be assumed.

P_D

= the pressure occurring coincident with the reversing dynamic load

(4) The range of the resultant moment M_{AM} and the amplitude of the longitudinal force F_{AM} resulting from the anchor motions due to earthquake and other reversing type dynamic loading shall not exceed the following:

$$C_2 \frac{M_{AM} D_O}{2I} < S_1$$

$$\frac{F_{AM}}{A_M} < S_2$$

where

A_M	= cross-sectional area of metal in the piping component wall
S_1	= $6S_m$
S_2	= $1.0S_m$

(5) Piping displacements shall satisfy Design Specification limitations.

(c) As an alternative to NB-3656(a) and (b), the rules contained in Appendix F may be used in evaluating these service loadings independently of all other Design and Service Loadings.

Page 155

NB-3657 Test Loadings

The evaluation of Test Loadings shall be carried out in accordance with NB-3226.

NB-3658 Analysis of Flanged Joints

The pressure design of flanged joints is covered by NB-3647.1. Flanged joints subjected to combinations of moment and pressure shall meet the requirements of this paragraph. In addition, the pipe-to-flange welds shall meet the requirements of NB-3652 through NB-3656 using appropriate stress indices from Table NB-3681(a)-1. Flanged joints using flanges, bolting, and gaskets as specified in ANSI B16.5 and using a bolt material having an S_m value at 100°F (38°C) not less than 20.0 ksi (138 MPa) may be analyzed in accordance with the following rules or in accordance with NB-3200. Other flanged joints shall be analyzed in accordance with NB-3200.

[98]

NB-3658.1 Design Limits, Levels A and B Service Limits

(a) The pressure shall not exceed the rated pressure for Level A Service Limits or 1.1 times the rated pressure for Level B Service Limits.

(b) The bolting shall meet the requirements of NB-3232. In addition, the limitations given by Eqs. (15) and (16) shall be met:

$$(15) M_{fs} \leq 3125 (S_y/36,000) C A_b$$

where

A_b	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, sq in.
C	= diameter of bolt circle, in.
M_{fs}	= bending or torsional moment (considered separately) applied to the joint due to weight, thermal expansion of the piping, sustained anchor movements, relief valve steady-state thrust, and other sustained mechanical loads applied to the flanged joint during the design or service conditions, in.-lb. If cold springing is used, the moment may be reduced to the extent permitted by NB-3672.8.
S_y	= yield strength of flange material at Design Temperature (Section II, Part D, Subpart 1, Table Y-1), psi. The value of $S_y/36,000$ shall not be taken as greater than unity.

$$M_{fd} \leq 6250(S_y / 36,000) CA_b \quad (16)$$

(16)

where

M_{fd} = bending or torsional moment (considered separately) as defined for M_{fs} , but including dynamic loadings, in.-lb

[98]

[98]

NB-3658.2 Level C Service Limits

(a) The pressure shall not exceed 1.5 times the rated pressure.

(b) The limitation given by Eq. (17) shall be met:

$$M_{fd} \leq [11,250A_b - (\pi/16)D_f^2 P_{fd}] C(S_y / 36,000) \quad (17)$$

(17)

where

D_f = outside diameter of raised face, in.

P_{fd} = pressure concurrent with M_{fd} , psi

M_{fd} , C , S_y , the limitation on $S_y/36,000$, and A_b are defined in NB-3658.1(b).

[98]

[98]

NB-3658.3 Level D Service Limits

(a) The pressure shall not exceed 2.0 times the rated pressure.

(b) The limitation given by Eq. (17) of NB-3658.2(b) shall be met, where P_{fd} and M_{fd} are pressures, psi, and moments, in.-lb, occurring concurrently.

[98]

NB-3658.4 Test Loadings.

Analysis for Test Loadings is not required.

NB-3660 DESIGN OF WELDS

NB-3661 Welded Joints

NB-3661.1 General Requirements.

Welded joints shall be made in accordance with NB-4200.

NB-3661.2 Socket Welds²⁴

(a) Socket welded piping joints shall be limited to pipe sizes of 2 in. and less.

(b) Socket welded piping joints shall conform to the requirements specified in ANSI B16.11, the applicable standards listed in Table NB-3132-1, and Fig. NB-4427-1. A gap of approximately $\frac{1}{16}$ in. (1.6 mm) shall be provided between the end of the pipe and the bottom of the socket before welding.

24 Socket welds shall not be used where the existence of crevices could accelerate corrosion.

NB-3661.3 Partial Penetration Welds for Branch Connections

(a) Partial penetration welds are allowed for branch connections in which there are substantially no piping reactions transmitted from the branch, such as openings

Page 156

for instrumentation. The ratio of nominal pipe size of the main pipe to that of the branch shall not be less than 10. Maximum branch size shall not exceed 2 in. nominal pipe size (DN 50). For such branch connections, all reinforcing shall be an integral part of the pipe penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the branch. Reinforcing requirements of NB-3643 shall be met.

(b) Partial penetration branch connections shall be groove welds as shown in Fig. NB-4244(d)-1. These welds shall be capable of being examined in accordance with the requirements of NB-5245.

(c) The inner corners of finished openings, in which the branch does not extend beyond the inner surface of the pipe penetrated, shall be rounded to a minimum radius of one-fourth the thickness t_n of the penetrating part or $\frac{3}{4}$ in. (19 mm), whichever is smaller. The corners of the end of each branch extending less than $\sqrt{d}t_n$ beyond the inner surface of the pipe penetrated shall be rounded to radius of one-half the thickness t_n of the penetrating part or $\frac{3}{4}$ in. (19 mm), whichever is smaller.

NB-3670 SPECIAL PIPING REQUIREMENTS

NB-3671 Selection and Limitation of Nonwelded Piping Joints

The type of piping joint used shall be suitable for the Design Loadings and shall be selected with consideration of joint tightness, mechanical strength, and the nature of the fluid handled. Piping joints shall conform to the requirements of this Subsection with leak tightness being a consideration in selection and design of joints for piping systems to satisfy the requirements of the Design Specifications.

NB-3671.1 Flanged Joints.

Flanged joints are permitted.

NB-3671.2 Expanded Joints.

Expanded joints shall not be used.

NB-3671.3 Threaded Joints.

Threaded joints in which the threads provide the only seal shall not be used. If a seal weld is employed as the sealing medium, the stress analysis of the joint must include the stresses in the weld resulting from the relative deflections of the mated parts.

NB-3671.4 Flared, Flareless, and Compression Joints.

Flared, flareless, and compression type tubing fittings may be used for tubing sizes not exceeding 1 in. O.D. within the limitations of applicable standards and specifications listed in Table NB-3132-1 and requirements (b) and (c) below. In the absence of such standards or specifications, the Designer shall determine that the type of fitting selected is adequate and safe for the Design Loadings in accordance with the requirements of (a), (b), and (c) below.

(a) The pressure design shall meet the requirements of NB-3649.

(b) Fittings and their joints shall be suitable for the tubing with which they are to be used in accordance with the minimum wall thickness of the tubing and method of assembly recommended by the manufacturer.

(c) Fittings shall not be used in services that exceed the manufacturer's maximum pressure-temperature recommendations.

NB-3671.5 Caulked Joints.

Caulked or leaded joints shall not be used.

NB-3671.6 Brazed and Soldered Joints

(a) *Brazed Joints*

(1) Brazed joints of a maximum nominal pipe size of 1 in. may be used only at dead end instrument connections and in special applications where space and geometry conditions prevent the use of joints permitted under NB-3661.2, NB-3661.3, and NB-3671.4. The depth of socket shall be at least equal to that required for socket welding fittings and shall be of sufficient depth to develop a rupture strength equal to that of the pipe at Design Temperature (NB-4500).

(2) Brazed joints that depend upon a fillet rather than a capillary type filler addition are not acceptable.

(3) Brazed joints shall not be used in systems containing flammable fluids or in areas where fire hazards are involved.

(b) *Soldered Joints.* Soldered joints shall not be used.

NB-3671.7 Sleeve Coupled and Other Patented Joints.

Mechanical joints, for which no standards exist, and other patented joints may be used provided the requirements of (a), (b), and (c) below are met.

(a) Provision is made to prevent separation of the joints under all Service Loadings.

(b) They are accessible for maintenance, removal, and replacement after service.

(c) Either of the following two criteria are met.

(1) A prototype joint has been subjected to performance tests to determine the safety of the joint under simulated service conditions. When vibration, fatigue, cyclic conditions, low temperature, thermal expansion, or hydraulic shock is anticipated, the applicable conditions shall be incorporated in the tests. The mechanical joints shall be sufficiently leak tight to satisfy the requirements of the Design Specifications.

Page 157

(2) Joints are designed in accordance with the rules of NB-3200.

NB-3672 Expansion and Flexibility

(a) In addition to meeting the design requirements for pressure, weight, and other loadings, piping systems shall be

designed to absorb or resist thermal expansion or contraction or similar movements imposed by other sources and shall meet the criteria for allowable stress intensity as specified in NB-3611. Piping systems shall be designed to have sufficient flexibility to prevent the movements from causing:

- (1) failure of piping or anchors from overstress or overstrain;
- (2) leakage at joints;
- (3) detrimental distortion of connected equipment resulting from excessive thrusts and moments.

(b) The effects of stresses, caused by pressure, thermal expansion, and other loads and their stress intensification factors, shall be considered cumulatively.

NB-3672.1 Properties.

Thermal expansion data and moduli of elasticity shall be determined from Section II, Part D, Subpart 2, Tables TE and TM, which cover more commonly used piping materials. For materials not included in these tables, reference shall be to authoritative source data, such as publications of the National Institute of Standards and Technology.

NB-3672.2 Unit Thermal Expansion Range.

The unit thermal expansion range in in./100 ft, used in calculating the expansion range, shall be determined from Section II, Part D, Subpart 2, Tables TE as the algebraic difference between the unit expansion shown for the highest metal temperature and that for the lowest metal temperature resulting from service or shutdown conditions.

NB-3672.3 Moduli of Elasticity.

The moduli of elasticity for ferrous and nonferrous materials shall be as given in Section II, Part D, Subpart 2, Tables TM.

NB-3672.4 Poisson's Ratio.

When required for flexibility calculations, Poisson's ratio shall be taken as 0.3 for all metals at all temperatures.

NB-3672.5 Stresses.

Flexibility calculations of the moments and forces in the piping system due to thermal expansion and end motions shall be based on the hot modulus E_h . Calculations for the expansion stresses shall be based on the least cross-sectional area of the pipe or fitting, using nominal dimensions. The expansion stress computed from the forces and moments shall be multiplied by the ratio E_c/E_h . The effect of expansion stresses in combination with stresses from other causes shall be evaluated in accordance with NB-3611 or NB-3630.

NB-3672.6 Method of Analysis.

All systems shall be analyzed for adequate flexibility by a rigorous structural analysis unless they can be judged technically adequate by an engineering comparison with previously analyzed systems.

NB-3672.7 Basic Assumptions and Requirements

(a) When calculating the flexibility of a piping system between anchor points, the system between the anchor points shall be treated as a whole. The significance of all parts of the line and of all restraints, such as supports or guides, including intermediate restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, shall be considered.

(b) Comprehensive calculations shall take into account the flexibility factors and stress indices found to exist in piping products other than straight pipe. Credit may be taken where extra flexibility exists in the piping system. Flexibility factors and stress indices are given in NB-3680.

(c) The total expansion range shall be used in all calculations whether or not the piping is cold sprung. Not only the expansion of the line itself, but also linear and angular movements of the equipment and supports to which it is attached,

shall be considered.

(d) Where assumptions are used in calculations or model tests, the likelihood of underestimates of forces, moments, and stresses, including the effects of stress intensification, shall be evaluated.

NB-3672.8 Cold Springing.

Cold springing provides a beneficial effect in assisting a system to attain its most favorable position sooner. The effect of cold springing shall be analyzed as any other movement in the system is analyzed. The maximum stress allowed due to cold springing is $2.0S_m$ at the cold spring temperature. Since the usual erection procedures may not permit accurate determination of cold spring in a piping system, the allowable reduction of forces and moments at anchors or equipment caused by cold springing shall be limited to no more than two-thirds of the calculated reduction.

NB-3674 Design of Pipe Supporting Elements

Supporting elements, including hangers, anchors, and sliding supports, shall be designed in accordance with the requirements of Subsection NF.

Page 158

NB-3677 Pressure Relief Piping

NB-3677.1 General Requirements.

Pressure relief piping within the scope of this Subsection shall be supported to sustain reaction forces and shall conform to the requirements of the following subparagraphs.

NB-3677.2 Piping to Pressure Relieving Safety Devices

(a) Piping that connects a pressure relieving safety device to a piping system shall comply with all the requirements of the class of piping of the system which it is designated to relieve.

(b) There shall be no intervening stop valves between systems being protected and their protective device or devices except as provided for in NB-7142.

NB-3677.3 Discharge Piping From Pressure Relieving Safety Devices

(a) Discharge piping from pressure relieving safety devices shall comply with the requirements applicable to the conditions under which it operates.

(b) There shall be no intervening stop valve between the protective device or devices and the point of discharge except as provided for in NB-7142.

(c) The effluent from relief devices may be discharged outside the containment only if adequate provisions are made for the safe disposal of the effluent. It shall not impinge on other piping or structure or equipment and shall be directed away from platforms and other areas which might be used by personnel.

(d) It is recommended that individual discharge lines be used, but, if two or more reliefs are combined, the discharge piping shall be designed with sufficient flow area to prevent undue back pressure.

(e) When the umbrella or drip pan type of connection between the pressure relieving safety device and the discharge piping is used, the discharge piping shall be so designed as to prevent binding due to expansion movements and shall be so dimensioned as to prevent the possibility of blow back of the effluent. Individual discharge lines shall be used in this application. Drainage shall be provided to remove water collected above the safety valve seat.

(f) Discharge lines from pressure relieving safety devices within the scope of this Subsection shall be designed to facilitate drainage if there is any possibility that the effluent can contain liquid.

NB-3680 STRESS INDICES AND FLEXIBILITY FACTORS

NB-3681 Scope

(a) There are two types of analyses allowed by the rules of this Subarticle. The applicable B , C , and K indices to be used with Eqs. (9), (10), and (11) of NB-3650 are given in Table NB-3681(a)-1. The applicable indices to be used with the detailed analysis of NB-3200 are given in NB-3685 and NB-3338.

(b) Methods of determining flexibility factors for some commonly used piping products are given in NB-3686.

(c) Values of stress indices are tabulated for commonly used piping products and joints. Unless specific data, which shall be referenced in the Design Report, exist that would warrant lower stress indices than those tabulated or higher flexibility factors than those calculated by the methods of NB-3686, the stress indices given shall be used as minimums and the flexibility factors shall be used as maximums.

(d) For piping products not covered by NB-3680, stress indices and flexibility factors shall be established by experimental analysis (Appendix II) or theoretical analysis. Such test data or theoretical analysis shall be included in the Design Report.

(e) When determining stress indices by experimental methods, the nominal stress at the point under consideration (crack site, point of maximum stress intensity, etc.) shall be used.

NB-3682 Definitions of Stress Indices and Flexibility Factors

(a) The general definition of a stress index for mechanical loads is:

$$B, C, K, \text{ or } i = \frac{\sigma}{S}$$

where

S	= nominal stress, psi, due to load L
σ	= elastic stress, psi, due to load L

For B indices, σ represents the stress magnitude corresponding to a limit load. For C or K indices, σ represents the maximum stress intensity due to load L . For i factors, σ represents the principal stress at a particular point, surface, and direction due to load L . The nominal stress S is defined in detail in the tables of stress indices.

(b) The general definition of a stress index for thermal loads is:

$$C \text{ or } K = \frac{\sigma}{E\alpha\Delta T}$$

where

E

= modulus of elasticity, psi

Page 159

Page 160

α

= coefficient of thermal expansion

ΔT

= thermal difference, °F

σ

= maximum stress intensity, psi, due to thermal difference ΔT

[98]

TABLE NB-3681(a)-1 STRESS INDICES¹ FOR USE WITH EQUATIONS IN NB-3650

The values of E , α , and ΔT are defined in detail in NB-3650.

(c) Flexibility factors are identified herein by k with appropriate subscripts. The general definition of a flexibility factor

is:

$$k = \theta_{ab} / \theta_{\text{nom}}$$

where

θ_{ab} = rotation of end a , with respect to end b , due to a moment load M and in the direction of the moment M

θ_{nom} = nominal rotation due to moment load M

The flexibility factor k and nominal rotation θ_{nom} are defined in detail for specific components in NB-3686.

NB-3683 Stress Indices for Use With NB-3650

The stress indices given herein and in Table NB-3681(a)-1 and subject to the additional restrictions specified herein are to be used with the analysis methods of NB-3650. For piping products outside the applicable range, stress indices shall be established in accordance with NB-3681.

[98]

NB-3683.1 Nomenclature

(a) *Dimensions.* Nominal dimensions as specified in the dimensional standards of Table NB-3132-1 shall be used for calculating the numerical values of the stress indices given herein and in Table NB-3681(a)-1, and for evaluating Eqs. (9) through (14) of NB-3650. For ANSI B16.9, ANSI B16.28, or MSS SP-87 piping products, the nominal dimensions of the equivalent pipe (for example, Schedule 40) as certified by the manufacturer shall be used. Not more than one equivalent pipe size shall be certified for given product items of the same size, shape, and weight.

For piping products such as reducers and tapered-wall transitions which have different dimensions at either end, the nominal dimensions of the large or small end, whichever gives the larger value of D_o/t , shall be used. Dimensional terms are defined as follows:

D_o	= nominal outside diameter of pipe, in.
D_i	= nominal inside diameter of pipe, in.
D_m	= mean diameter of designated run pipe, in. [see NB-3683.8(c) and Fig. NB-3643.3(a)-1] = $2R_m = (D_o - T_r)$
D_{max}	= maximum outside diameter of cross section, in.
D_{min}	= minimum outside diameter of cross section, in.
D_1	= nominal outside diameter at large end of concentric and eccentric reducers, in. (see NB-3683.6)
D_2	= nominal outside diameter at small end of concentric and eccentric reducers, in. (see NB-3683.6)
d_o	= nominal outside diameter of attached branch pipe, in.
d_i	= nominal inside diameter of branch, in.
d_m	= nominal mean diameter of reinforced or unreinforced branch, in. [see NB-3683.8(c)] = $(d_i + t_n)$
h	= characteristic bend parameter of a curved pipe or butt welding elbow

	$= tR/r_m^2$
I	= moment of inertia of pipe, in. ⁴ $= 0.0491 (D_o^4 - D_i^4)$
L_1	= height of nozzle reinforcement for branch connections, in. [see Fig. NB-3643.3(a)-1]
L_1, L_2	= length of cylindrical portion at the large end and small end of a reducer, respectively (see NB-3683.6)
R	= nominal bend radius of curved pipe or elbow, in.
R_m	= mean radius of designated run pipe, in. [see NB-3683.8 and Fig. NB-3643.3(a)-1] $= (D_o - T_r)/2$
r_i	= inside radius of branch, in. [see Fig. NB-3643.3(a)-1] $= d_i/2$
r_m	= mean pipe radius, in. $= (D_o - t)/2$
r'_m	= mean radius of attached branch pipe, in. [see Fig. NB-3643.3(a)-1] $= (d_o - T_b)/2$
r_p	= outside radius of reinforced nozzle or branch connection, in. [see Fig. NB-3643.3(a)-1]
r_1, r_2, r_3	= designated radii for reinforced branch connections, concentric and eccentric reducers, in. [see NB-3683.6, NB-3683.8, and Fig. NB-3643.3(a)-1]
T_b	= wall thickness of branch connection reinforcement, in. [see Fig. NB-3643.3(a)-1]
T_b	= nominal wall thickness of attached branch pipe, in. [see Fig. NB-3643.3(a)-1]
T_r	= nominal wall thickness of designated run pipe, in. [see Fig. NB-3643.3(a)-1]
t	= nominal wall thickness of pipe, in. For piping products purchased to a minimum wall specification, the nominal wall thickness

shall be taken as 1.14 times the minimum wall.

$t_{\max}$	= maximum wall thickness of a welding transition within a distance of $\sqrt{D_o t}$ from the welding end [see NB-3683.5(b)]
t_n	= wall thickness of nozzle or branch connection reinforcement, in. (see NB-3683.8; also used for concentric and eccentric reducers, see NB-3683.6)
t_1	= nominal wall thickness at large end of concentric and

	eccentric reducers, in. (see NB-3683.6)
t_2	= nominal wall thickness at small end of concentric and eccentric reducers, in. (see NB-3683.6)
t_{1m}, t_{2m}	= minimum wall thickness at the large end and small end of a reducer, respectively, that is required to resist the Design Pressure P in accordance with Eq. (1), NB-3641.1
Z	= section modulus of pipe, in. ³ = $2I/D_o$
Z_b	= approximate section modulus of attached branch pipe, in. ³ = $\pi(r'_m)^2 T'_b$
Z_r	= approximate section modulus of designated run pipe, in. ³ = $\pi(R_m)^2 T_r$
α	= cone angle of concentric and eccentric reducers, deg. (see NB-3683.6)
Δ	= radial weld shrinkage measured from the nominal outside surface, in.
θ_n	= slope of nozzle-to-pipe transition for branch connections, deg. [see Fig. NB-3643.3(a)-1]

(b) *Material Properties.* Unless otherwise specified, material properties at the appropriate temperature, as given in Section II, Part D, Subparts 1 and 2, shall be used. Terms are defined as follows:

E	= modulus of elasticity for the material at room temperature, psi, taken from Tables TM
M	= materials constant = 2, for ferritic steels and nonferrous materials except nickel-chrome-iron alloys and nickel-iron-chrome alloys = 2.7, for austenitic steel, nickel-chrome-iron alloys and nickel-iron-chrome alloys [see NB-3683.2(b)]
S_y	= yield strength of the material at the Design Temperature, psi, taken from Table Y-1
ν	= Poisson's ratio = 0.3

FIG. NB-3683.1(c)-1

FIG. NB-3683.1(c)-1

(c) *Connecting Welds.* Connecting welds in accordance with the requirements of this Subsection are defined as either *flush* or *as-welded* welds.

(1) *Flush welds* are those welds with contours as defined in Fig. NB-3683.1(c)-1. The total thickness (both inside and outside) of the weld reinforcement shall not exceed $0.1t$. There shall be no concavity on either the interior or exterior surfaces and the finished contour shall not have any slope greater than 7 deg. where the angle is measured from a tangent to the surface of the pipe or on the tapered transition side of the weld to the nominal transition surface.

(2) *As-welded welds* are those welds not meeting the special requirements of flush welds.

(d) *Loadings.* Loadings for which stress indices are given include internal pressure, bending and torsional moments, and temperature differences. The indices are intended to be sufficiently conservative to account also for the effects of transverse shear forces normally encountered in flexible piping systems. If, however, thrust or shear forces account for a significant portion of the loading on a given piping product, the effect of these forces shall be included in the design analysis. The values of the moments and forces shall be obtained from an analysis of the piping system in accordance with NB-3672. Loading terms are defined as follows:

$$M_1, M_2, M_3$$

= orthogonal moment loading components at a given position in a piping system, in.-lb

$$M_{ij}$$

= orthogonal moment components of a tee or branch connection as shown in Fig. NB-3683.1(d)-1 where $i = x, y, z$ and $j = 1, 2, 3$

$$M_t$$

= resultant moment loading applied during the specified operating cycle for straight-through products such as straight pipe, curved pipe or elbows, and concentric reducers

P

$$= \sqrt{M_1^2 + M_2^2 + M_3^2}$$

= Design Pressure, psi

Page 162

P_o

= range of service pressure, psi

P^*

= maximum value of pressure in the load cycle under consideration, psi

FIG. NB-3683.1(d)-1

FIG. NB-3683.1(d)-1

The moment components M_{x1} , M_{x2} , M_{y1} , M_{y2} , M_{z1} , and M_{z2} for the run are calculated at the intersection of the run and branch center lines. The moment components M_{x3} , M_{y3} , and M_{z3} for a branch connection where $d_o/D_o \leq 0.5$ may be calculated for a point on the branch center line at a distance $D_o/2$ from the intersection of the run and branch center lines. Otherwise, M_{x3} , M_{y3} , and M_{z3} are calculated at the intersection of the run and branch center lines.

M_b

= resultant moment on the branch for branch connections or tees, in.-lb

$$= \sqrt{M_{x3}^2 + M_{y3}^2 + M_{z3}^2}$$

M

b	expansion and thermal anchor movements
M_r	= resultant moment on the run for branch connections or tees, in.-lb $= \sqrt{M_{xr}^2 + M_{yr}^2 + M_{zr}^2}$
M_r^*	= same as M_r except it includes only moments due to thermal expansion and thermal anchor movements
M_{xr}, M_{yr}, M_{zr}	= run moment components for use with the stress indices of NB-3683.9. Their numerical values are calculated as follows. If M_{i1} and M_{i2} where $i = x, y, z$ have the same algebraic sign (+/-), then M_{ir} equals zero. If M_{i1} and M_{i2} have opposite algebraic signs, then M_{ir} equals the smaller of M_{i1} or M_{i2} . If M_{i1} and M_{i2} are unsigned, then M_{ir} may be taken as the smaller of M_{i1} or M_{i2} . Combination of signed and unsigned moments from different load sources shall be done after determination of M_{ir} .

For branch connections or tees, the pressure term of Eqs. (9), (10), (11), and (13) shall be replaced by the following terms:

For Eq. (9): $B_1 (PD_o/2T_r)$

For Eqs. (10) and (13): $C_1 (P_o D_o/2T_r)$

For Eq. (11): $K_1 C_1 (P_o D_o/2T_r)$

For branch connections or tees, the moment term of Eqs. (9) through (13) shall be replaced by the following pairs of terms:

For Eq. (9): $B_{2b} (M_b/Z_b) + B_{2r} (M_r/Z_r)$

For Eqs. (10) and (13): $C_{2b} (M_b/Z_b) + C_{2r} (M_r/Z_r)$

For Eq. (11): $C_{2b} K_{2b} (M_b/Z_b) + C_{2r} K_{2r} (M_r/Z_r)$

For Eq. (12): $C_{2b} (M_b^*/Z_b) + C_{2r} (M_r^*/Z_r)$

where the approximate section moduli are:

$$Z_b = \pi (t'_m)^2 T_b$$

$$Z_r = \pi (R_m)^2 T_r$$

[98]

[98]

NB-3683.2 Applicability of Indices - General.

The B , C , and K stress indices given herein and in Table NB-3681(a)-1 predict stresses at a weld joint or within the body of a particular product. The stress indices given for ANSI B16.9, ANSI B16.28, and MSS SP-87 piping products apply only to seamless products with no connections, attachments, or other extraneous stress raisers on the body thereof. The stress indices for welds are not applicable if the radial weld shrinkage Δ is greater than $0.25t$.

For products with longitudinal butt welds, the K_1 , K_2 , and K_3 indices shown shall be multiplied by 1.1 for flush welds or by 1.3 for as-welded welds. At the intersection of a longitudinal butt weld in straight pipe with a girth butt weld or girth fillet weld, the C_1 , K_1 , C_2 , K_2 , and K_3 indices shall be taken as the product of the respective indices.

(a) *Abutting Products.* In general and unless otherwise specified, it is not required to take the product of stress indices

for two piping products, such as a tee and a reducer when welded together, or a tee and a girth butt weld. The piping product and the weld shall be qualified separately.

For curved pipe or butt welding elbows welded together or joined by a piece of straight pipe less than one pipe diameter long, the stress indices shall be taken

Page 163

as the product of the indices for the elbow or curved pipe and the indices for the girth butt weld, except for B_1 and C_3 which are exempted.

(b) *Out-of-Round Products.* The stress indices given in Table NB-3681(a)-1 are applicable for products and welds with out-of-roundness not greater than $0.08t$ where out-of-roundness is defined as $D_{\max} - D_{\min}$. For straight pipe, curved pipe, longitudinal butt welds in straight pipe, girth butt welds, NB-4250 transitions, and 1:3 transitions not meeting this requirement, the stress indices shall be modified as specified below.

(1) If the cross section is out-of-round but with no discontinuity in radius, e.g., an elliptical cross section, an acceptable value of K_1 may be obtained by multiplying the tabulated values of K_1 by the factor F_{1a} :

$$F_{1a} = 1 + \frac{D_{\max} - D_{\min}}{t} \left[\frac{1.5}{1 + 0.455(D_o/t)^3(p/E)} \right]$$

where

D_o	= nominal outside diameter, in.
E	= modulus of elasticity of material at room temperature, psi
p	= internal pressure (use maximum value of pressure in the load cycle under consideration), psi

Other symbols are defined in (b) above.

(2) If there are discontinuities in radius, e.g., a flat spot, and if $D_{\max} - D_{\min}$ is not greater than $0.08D_o$, an acceptable value of K_1 may be obtained by multiplying the tabulated values of K_1 by the factor F_{1b} :

$$F_{1b} = 1 + MS_y/(PD_o/2t)$$

where

M	= 2, for ferritic steels and nonferrous materials except nickel-chromium-iron alloys and nickel-iron-chromium alloys = 2.7, for austenitic steel, nickel-chromium-iron alloys, and nickel-iron-chromium alloys
P	= Design Pressure, psi
S_y	= yield strength at Design Temperature (Section II, Part D, Subpart 1, Table Y-1), psi

D and t are defined in (a) and (b) above.

[98]

NB-3683.3 Straight Pipe Remote From Welds.

The stress indices given in Table NB-3681(a)-1 apply for straight pipe remote from welds or other discontinuities, except as modified by NB-3683.2.

[98]

NB-3683.4 Welds

(a) *Longitudinal Butt Welds.* The stress indices given in Table NB-3681(a)-1 are applicable for longitudinal butt welds in straight pipe, except as modified in NB-3683.2.

(b) *Girth Butt Welds.* The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to girth butt welds connecting abutting products for which the wall thickness is between $0.875t$ and $1.1t$ for an axial distance of $\sqrt{D_o t}$ from the welding ends. Girth welds may also exhibit a reduction in diameter due to shrinkage of the weld material during cooling. The indices are not applicable if Δ/t is greater than 0.25 where Δ is the radial shrinkage measured from the nominal outside surface.

For as-welded girth butt welds joining items with nominal wall thicknesses $t < 0.237$, the C_2 index shall be taken as:

$$C_2 = 1.0 + 0.094/t \text{ but not } > 2.1$$

(c) *Girth Fillet Welds.* The stress indices given in Table NB-3681(a)-1 are applicable to girth fillet welds used to attach socket welding fittings, socket welding valves, slip-on flanges, or socket welding flanges, except as added to or modified in NB-3683.1, and in (1) and (2) below.

(1) *Primary Stress Indices.* The B_1 and B_2 indices shall be taken as:

$$B_1 = 0.75(t_n/C_x) \geq 0.5$$

$$B_2 = 1.5(t_n/C_x) \geq 1.0$$

where C_x and t_n are defined in Fig. NB-4427-1, sketches (c) and (d). In Fig. NB-4427-1 sketch (c), C_x shall be taken as $X_{\min}$ and $C_x \geq 1.25t_n$. In Fig. NB-4427-1 sketch (d), $C_x \geq 0.75t_n$. For unequal leg lengths use the smaller leg length for C_x .

(2) *Primary Plus Secondary Stress Indices.* The C_1 and C_2 indices shall be taken as:

$$C_1 = 1.8(t_n/C_x) \geq 1.4$$

$$C_2 = 2.1(t_n/C_x) \geq 1.3$$

[98]

[98]

NB-3683.5 Welded Transitions.

The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable for NB-4250 welded transitions as defined under NB-3683.5(a) and for 1:3 welded transitions as defined under NB-3683.5 (b). Girth butt welds may also exhibit a reduction in diameter

Page 164

due to shrinkage of the weld material during cooling. The indices are not applicable if Δ/t is greater than 0.25.

(a) *NB-4250 Transitions.* The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to girth butt welds between a product for which the wall thickness is between $0.875t$ and $1.1t$ for an axial distance of $\sqrt{D_o t}$ from the welding end and an abutting product for which the welding end is within the envelope of Fig. NB-4250-1, but with inside and outside surfaces that do not slope in the same direction. For transitions meeting these requirements, the C_1 , C_2 , and C_3 indices shall be taken as:

$$C_1 = 0.5 + 0.33 (D_o/t)^{0.3} + 0.047/t \text{ but not } > 1.8$$

$$C_2 = 1.7 + 0.094/t \text{ but not } > 2.1$$

$$C_3 = 1.0 + 0.03 (D_o/t) \text{ but not } > 2.0$$

For flush welds and for as-welded joints between items with $t > 0.237$, C_1 and C_2 shall be taken as:

$$C_1 = 0.5 + 0.33 (D_o/t)^{0.3} \text{ but not } > 1.8$$

$$C_2 = 1.7$$

(b) *Transitions Within a 1:3 Slope.* The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable for girth butt welds between a product for which the wall thickness is between $0.875t$ and $1.1t$ for an axial distance of $\sqrt{D_o t}$ from the welding end and an abutting product for which the welding end is within an envelope defined by a 1:3 slope on the inside, outside, or both surfaces for an axial distance of $\sqrt{D_o t}$, but with inside and outside surfaces that do not slope in the same direction. For transitions meeting these requirements, the C_1 , C_2 and C_3 indices shall be taken as:

$$C_1 = 1.0 + 0.047/t \text{ but not } > 1.8$$

$$C_2 = t_{\max}/t + 0.094/t \text{ but not } > \text{the smaller of } (1.33 + 0.04\sqrt{D_o t}/t + 0.094/t) \text{ or } 2.1$$

$$C_3 = 0.35 (t_{\max}/t) + 0.25 \text{ but not } > 2.0$$

where $t_{\max}$ is the maximum wall thickness within the transition zone. If $(t_{\max}/t) \leq 1.10$, the stress indices given in NB-3683.4(b) for girth butt welds may be used. For flush welds and for as-welded joints between items with $t > 0.237$, C_1 and C_2 shall be taken as:

$$C_1 = 1.0$$

$$C_2 = t_{\max}/t \text{ but not } > \text{the smaller of } (1.33 + 0.04\sqrt{D_o t}/t) \text{ or } 2.1$$

[98]

[98]

NB-3683.6 Concentric and Eccentric Reducers.

The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to butt welding reducers manufactured to the requirements of ANSI B16.9 or MSS SP-87 if the cone angle α defined in Fig. NB-3683.6-1 is less than 60 deg. and if the wall thickness is not less than t_{lm} throughout the body of the reducer, except in and immediately adjacent to the cylindrical portion on the small end where the thickness shall not be less than t_{2m} . The wall thicknesses t_{lm} and t_{2m} are the minimum thicknesses required to resist the Design Pressure P at the large end and small end, respectively, in accordance with Eq. (1) of NB-3641.1. For eccentric reducers, the dimensions shown in Fig. NB-3683.6-1 are to be taken at the location on the circumference where α is the maximum.

(a) *Primary Stress Indices.* The B_1 stress indices given in (1) or (2) below shall be used depending on the cone angle α .

(1) $B_1 = 0.5$ for $\alpha \leq 30$ deg.

(2) $B_1 = 1.0$ for $30 \text{ deg.} < \alpha \leq 60 \text{ deg.}$

(b) *Primary Plus Secondary Stress Indices.* The C_1 and C_2 stress indices given in (1) or (2) below shall be used depending on the dimensions of the transition radii r_1 and r_2 .

(1) For reducers with r and $r \geq 0.1 D$:

$$C_2 = 1.0 + 0.36 \alpha^{0.4} (D_n/t_n)^{0.4(D_2/D_1 - 0.5)}$$

where D_n/t_n is the larger of D_1/t_1 and D_2/t_2 .

(2) For reducers with r_1 and/or $r_2 < 0.1D_1$:

$$C_1 = 1.0 + 0.00465 \alpha^{1.285} (D_n/t_n)^{0.39}$$

$$C_2 = 1.0 + 0.0185 \alpha \sqrt{D_n/t_n}$$

where D_n/t_n is the larger of D_1/t_1 and D_2/t_2

FIG. NB-3683.6-1

FIG. NB-3683.6-1

(c) *Peak Stress Indices.* The K_1 and K_2 indices given in (1), (2), or (3) below shall be used depending on the type of connecting weld and thickness dimensions.

(1) For reducers connected to pipe with flush girth butt welds:

$$K_1 = 1.1 - 0.1 \frac{L_m}{\sqrt{D_m} t_m} \text{ but not } < 1.0$$

$$K_2 = 1.1 - 0.1 \frac{L_m}{\sqrt{D_m} t_m} \text{ but not } < 1.0$$

where $\frac{L_m}{\sqrt{D_m} t_m}$ is the smaller of $\frac{L_1}{\sqrt{D_1} t_1}$ and $\frac{L_2}{\sqrt{D_2} t_2}$.

(2) For reducers connected to pipe with as-welded girth butt welds where t_1 and $t_2 > \frac{3}{16}$ in. (4.8 mm):

$$K_1 = 1.2 - 0.2 \frac{L_m}{\sqrt{D_m} t_m} \text{ but not } < 1.0$$

$$K_2 = 1.8 - 0.8 \frac{L_m}{\sqrt{D_m} t_m} \text{ but not } < 1.0$$

where $\frac{L_m}{\sqrt{D_m} t_m}$ is the smaller of $\frac{L_1}{\sqrt{D_1} t_1}$ and $\frac{L_2}{\sqrt{D_2} t_2}$.

(3) For reducers connected to pipe with as-welded girth butt welds where t_1 or $t_2 \leq \frac{3}{16}$ in. (4.8 mm):

$$K_1 = 1.2 - 0.2 \frac{L_m}{\sqrt{D_m} t_m} \text{ but not } < 1.0$$

$$K_2 = 2.5 - 1.5 L_m / \sqrt{D_m t_m} \text{ but not } < 1.0$$

where $L_m / \sqrt{D_m t_m}$ is the smaller of $L_1 / \sqrt{D_1 t_1}$ and $L_2 / \sqrt{D_2 t_2}$.

[98]

[98]

NB-3683.7 Curved Pipe or Butt Welding Elbows.

The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to curved pipe or butt welding elbows manufactured to the requirements of ANSI B16.9, ANSI B16.28, or MSS SP-87.

(a) *Primary Stress Index.* The B_1 and B_2 indices shall be taken as:

$$B_1 = -0.1 + 0.4h \text{ but not } < 0 \text{ nor } > 0.5$$

$$B_2 = 1.30/h^{2/3} \text{ but not } < 1.0$$

where

$$h = tR/r_m^2$$

(b) *Primary Plus Secondary Stress Indices.* The C_1 and C_2 indices shall be taken as:

$$C_1 = (2R - r_m)/2(R - r_m)$$

$$C_2 = 1.95/h^{2/3} \text{ but not } < 1.5$$

where

$$h = tR/r_m^2$$

[98]

[98]

NB-3683.8 Branch Connections per NB-3643.

The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to reinforced or unreinforced branch connections meeting the general requirements of NB-3643 and the additional requirements of NB-3683.8(a). Symbols are defined in NB-3683.1 and in Fig. NB-3643.3(a)-1.

(a) *Applicability.* The stress indices are applicable, provided the following limitations are met.

(1) For branch connections in a pipe, the arc distance measured between the centers of adjacent branches along the outside surface of the run pipe is not less than three times the sum of the two adjacent branch inside radii in the longitudinal direction, or is not less than two times the sum of the two adjacent branch radii along the circumference of the run pipe.

(2) The axis of the branch connection is normal to the run pipe surface.

(3) The run pipe radius-to-thickness ratio R_m/T_r is less than 50, and the branch-to-run radius ratio r'_m/R_m is less than 0.50.

(4) The inside corner radius r_1 [Fig. NB-3643.3(a)-1] for nominal pipe sizes greater than 4 in. NPS (DN 100) shall be between 10% and 50% of T_r . The

radius r_1 is not required for branch pipe sizes smaller than 4 in. NPS (DN 100).

(5) The branch-to-run fillet radius r_2 is not less than the larger of $T_b/2$, $T_r/2$, or $(T_b + y)/2$ [Fig. NB-3643.3(a)-1 sketch (c)].

(6) The branch-to-pipe fillet radius r_3 is not less than the larger of $0.002 \theta d_o$ or $2(\sin\theta)^3$ times offset [Fig. NB-3643.3(a)-1], where θ is expressed in deg.

(7) If L_1 equals or exceeds $0.5\sqrt{r_1 T_b}$, then r'_m can be taken as the radius to the center of T_b .

(b) *Primary Stress Indices.* The primary stress indices B_{2b} and B_{2r} shall be taken as:

$$B_{2b} = 0.5C_{2b} \text{ but not } < 1.0$$

$$B_{2r} = 0.75C_{2r} \text{ but not } < 1.0$$

(c) *Primary Plus Secondary Stress Indices.* The C_1 , C_{2b} , and C_{2r} indices [for moment loadings, see NB-3683.1(d)] shall be taken as:

$$C_1 = 1.4 \left(\frac{D_m}{T_r} \right)^{0.182} \left(\frac{d_m}{D_m} \right)^{0.367} \left(\frac{T_r}{t_n} \right)^{0.382} \left(\frac{t_n}{r_2} \right)^{0.148}$$

but not < 1.2

If $r_2/t_n > 12$, use $r_2/t_n = 12$ for computing C_1 .

$$C_{2b} = 3 \left(\frac{R_m}{T_r} \right)^{2/3} \left(\frac{r'_m}{R_m} \right)^{1/2} \left(\frac{T'_b}{T_r} \right) \left(\frac{r'_m}{r_p} \right)$$

but not < 1.5

$$C_{2r} = 1.15 \left(\frac{r'_m}{t_n} \right)^{1/4}$$

but not < 1.5

where

For Figs. NB-3643.3(a)-1 sketches (a) and (b):

$$t_n = T_b \text{ if } L_1 \geq 0.5 (d_m T_b)^{1/2}$$

$$= T_b \text{ if } L_1 < 0.5 (d_m T_b)^{1/2}$$

For Fig. NB-3643.3(a)-1 sketch (c):

$$t_n = T_b + (2/3)y \text{ if } \theta \leq 30^\circ$$

$$= T_b + 0.385 L_1 \text{ if } \theta > 30^\circ$$

For Fig. NB-3643.3(a)-1 sketch (d):

$$t_n = T_b = T_b$$

(d) *Peak Stress Indices.* The peak stress indices K_{2b} and K_{2r} for moment loadings [see NB-3683.1(d)] shall be taken as:

$$K_{2b} = 1.0$$

$$K_{2r} = 1.75$$

and $K_{2r} C_{2r}$ shall be a minimum of 2.65.

[98]

[98]

NB-3683.9 Butt Welding Tees.

The stress indices given in Table NB-3681(a)-1, except as modified herein and in NB-3683.2, are applicable to butt welding tees manufactured to the requirements of ANSI B16.9 or MSS SP-87.

(a) *Primary Stress Indices.* The primary stress indices B_{2b} and B_{2r} shall be taken as:

$$B_{2b} = 0.4 (R_m/T_r)^{2/3} \text{ but not } < 1.0$$

$$B_{2r} = 0.50 (R_m/T_r)^{2/3} \text{ but not } < 1.0$$

(b) *Primary Plus Secondary Stress Indices.* The C_{2b} and C_{2r} stress indices for moment loadings [see NB-3683.1(d)] shall be taken as:

$$C_{2b} = 0.67 (R_m/T_r)^{2/3} \text{ but not } < 2.0$$

$$C_{2r} = 0.67 (R_m/T_r)^{2/3} \text{ but not } < 2.0$$

(c) *Peak Stress Indices.* The peak stress indices K_{2b} and K_{2r} for moment loadings [see NB-3683.1(d)] shall be taken as:

$$K_{2b} = 1.0$$

$$K_{2r} = 1.0$$

[98]

NB-3684 Stress Indices for Detailed Analysis

The symbols for the stress components and their definitions are given in Fig. NB-3684-1. These definitions are applicable to all piping products, and the

Page 167

stress indices given in the tables in NB-3685 and NB-3338 are so defined.

σ_t = stress component in the plane of the section under consideration and parallel to the boundary of the section
 σ_n = stress component normal to the plane of the section
 σ_r = stress component normal to the boundary of the section
 σ = stress intensity (combined stress) at the point under consideration

FIG. NB-3684-1 DIRECTION OF STRESS COMPONENTS

FIG. NB-3684-1 DIRECTION OF STRESS COMPONENTS

NB-3685 Curved Pipe or Welding Elbows

[98]

NB-3685.1 Applicability of Indices.

The indices given in Tables NB-3685.1-1 and NB-3685.1-2 give stresses in curved pipe or elbows at points remote from girth or longitudinal welds or other local discontinuities. Stresses in curved pipe or welding elbows with local discontinuities, such as longitudinal welds, support lugs, and branch connections in the elbow, shall be obtained by

appropriate theoretical analysis or by experimental analysis in accordance with Appendix II.
[98]

[98]

NB-3685.2 Nomenclature (Fig. NB-3685.2-1)

A	= an additional thickness, in. (NB-3641.1)
D_i	= $D_o - 2(t_m - A)$, in.
D_o	= nominal outside diameter of cross section, in.
$D_1(D_2)$	= maximum (minimum) outside diameter of elbow with out-of-round cross section essentially describable as an ellipse or oval shape (Fig. NB-3685.2-1), in.
E	= modulus of elasticity, psi (Section II, Part D, Subpart 1, Tables TM)
P	= internal pressure, psi
R	= bend radius, in.
r	= mean cross section radius, in.
t_m	= minimum specified wall thickness, in.
Z	= section modulus of cross section, in. ³ = $0.0982 (D_o^4 - D_i^4)/D_o$
λ	= $t_m R / r^2 \sqrt{1 - \nu^2}$ (Table NB-3685.1-2 limited to $\lambda \geq 0.2$)

[98]

NB-3685.3 Stress From Stress Indices.

To obtain stresses from stress index:

Load

Multiply Stress Index by

Internal Pressure

M_x	P
M_y	$M_x/2Z$
M_z	M_y/Z
	M_z/Z

NB-3685.4 Classification of Stresses.

For analysis of a curved pipe or welding elbow to NB-3210, the following rules shall apply to the classification of stresses developed under a load controlled in-plane or out-of-plane moment as distinguished from a displacement controlled loading.

(a) The entire membrane portion of the axial, circumferential, and torsional stresses shall be considered as primary (P_L).

(b) Seventy-five percent of the through-wall bending stresses in both the axial and the circumferential directions shall be classified as primary (P_b). The remaining 25% shall be classified as secondary (Q). The stresses induced by displacement controlled in-plane or out-of-plane moments shall be classified as secondary (Q).

NB-3686

NB-3686.1 Straight Pipe.

For $M = M_1$ or M_2 (see Fig. NB-3686.1-1):

$$k = 1.0 \theta_{\text{nom}} = \frac{Ml}{EI}$$

For $M = M_3$ (see Fig. NB-3686.1-1):

$$k = 1.0 \theta_{\text{nom}} = \frac{Ml}{GJ}$$

In both cases

E	= modulus of elasticity, psi
G	= shear modulus, psi
I	= plane moment of inertia, in. ⁴
J	= polar moment of inertia, in. ⁴
l	= one pipe diameter

**TABLE NB-3685.1-1
CURVED PIPE OR WELDING END ELBOWS, INTERNAL PRESSURE**

Location	Surface	Stress Direction	Stress Index [Note (1)]
Round Cross Section			
ϕ	Inside	σ_n	$\left[\frac{D_o - 0.8(t_m - A)}{2(t_m - A)} \right] \left[\frac{0.5(2R + r \sin \phi)}{R + r \sin \phi} \right] = i_1$
ϕ	Mid	σ_n	
ϕ	Outside	σ_n	
ϕ	Inside	σ_t	$\frac{D_i}{4(t_m - A)} = i_2$
ϕ	Mid	σ_t	
ϕ	Outside	σ_t	
Out-of-Round Cross Section [Note (2)]			
α	Inside	σ_n	$i_1 + i_3$
α	Mid	σ_n	i_1
α	Outside	σ_n	$i_1 - i_3$
α	Inside	σ_t	$i_2 + 0.3 i_3$
α	Mid	σ_t	i_2
α	Outside	σ_t	$i_2 - 0.3 i_3$

NOTES:

(1) The radial stress σ_r is equal to $-P$ on the inside surface, to $-P/2$ on the midsurface, and to 0 on the outside surface.

(2) For out-of-round cross section:

$$i_3 = \left[\frac{D_o(D_3 - D_2)}{2t_m^2} \right] \left[\frac{1.5}{1 + 0.455(D_o/t_m)^3 (P/E)} \right] \cos 2\alpha$$

TABLE NB-3685.1-1 CURVED PIPE OR WELDING END ELBOWS, INTERNAL PRESSURE

NB-3686.2 Curved Pipe and Welding Elbows.

The flexibility factors may be calculated by the equations given below for k , provided²⁵ that:

(a) R/r is not less than 1.7;

(b) center line length $R\alpha$ is greater than $2r$;

²⁵ The flexibility of a curved pipe or welding elbow is reduced by end effects, provided either by the adjacent straight pipe or by the proximity of other relatively stiff members which inhibit ovalization of the cross section. In certain cases, these end effects may also reduce the stress. Additional work is underway to provide guidance for both flexibility factors and stress indices where end effects are significant.

(c) there are no flanges or other similar stiffeners within a distance r from either end of the curved section of pipe or from the ends of welding elbows. For M_1 or M_2 (see Fig. NB-3686.2-1):

$$k = \frac{1.65}{h} \left[\frac{1}{1 + (Pr/tE)X_k} \right]$$

but not less than 1.0, and

$$\theta_{\text{nom}} = \frac{R}{EI} \int_0^a M(d\alpha)$$

For M_3 (see Fig. NB-3686.2-1):

$$k = 1.0$$

$$\theta_{\text{nom}} = \frac{R}{GJ} \int_0^a M(d\alpha)$$

In both cases

E	= modulus of elasticity, psi
G	= shear modulus of elasticity, psi
h	= tR/r^2
I	= plane moment of inertia of cross section, in. ⁴
J	= polar moment of inertia of cross section, in. ⁴
P	= internal pressure, psi
R	= bend radius, in.
r	= pipe or elbow mean radius, in.
t	= pipe or elbow nominal wall thickness, in.

Page 169

X_k	= $6(r/t)^{4/3} (R/r)^{1/3}$
α	= arc angle, rad

TABLE NB-3685.1-2
CURVED PIPE OR WELDING END ELBOWS, MOMENT LOADING ($\lambda \geq 0.2$)

Location	Surface	Stress Direction	Stress Index [Note (1)]
Torsional Moment M_x			
All	All	τ_{nt} [Note (2)]	1.0
In-Plane or Out-of-Plane Moments M_y or M_z [Note (3)]			
ϕ	Outside	σ_n	$\nu\sigma_{tm} + \sigma_{nb}$
ϕ	Mid	σ_n	$\nu\sigma_{tm}$
ϕ	Inside	σ_n	$\nu\sigma_{tm} - \sigma_{nb}$
ϕ	Outside	σ_t	$\sigma_{tm} + \nu\sigma_{nb}$
ϕ	Mid	σ_t	σ_{tm}
ϕ	Inside	σ_t	$\sigma_{tm} - \nu\sigma_{nb}$

NOTES:

- (1) The radial stress σ_r is zero for all surfaces.
(2) τ_{nt} is a shear stress in the n - t plane and must be appropriately combined with the principal stresses σ_n and σ_t to obtain principal stresses due to combinations of M_x with M_y or M_z .
(3) Nomenclature for stress indices:

ν = Poisson's ratio

$$\left. \begin{aligned} \sigma_{tm} &= \sin \phi + [(1.5X_2 - 18.75) \sin 3\phi + 11.25 \sin 5\phi]/X_4 \\ \sigma_{nb} &= \lambda (9X_2 \cos 2\phi + 225 \cos 4\phi)/X_4 \end{aligned} \right\} \text{In-plane } M_z$$

$$\left. \begin{aligned} \sigma_{tm} &= \cos \phi + [(1.5X_2 - 18.75) \cos 3\phi + 11.25 \cos 5\phi]/X_4 \\ \sigma_{nb} &= -\lambda (9X_2 \sin 2\phi + 225 \sin 4\phi)/X_4 \end{aligned} \right\} \text{Out-of-plane } M_y$$

$$X_1 = 5 + 6\lambda^2 + 24\psi$$

$$X_2 = 17 + 600\lambda^2 + 480\psi$$

$$X_3 = X_1X_2 - 6.25$$

$$X_4 = (1 - \nu^2)(X_3 - 4.5X_2)$$

$$\lambda = t_m R / (r^2 \sqrt{1 - \nu^2}) \text{ (Equations are valid for } \lambda \geq 0.2 \text{ only.)}$$

$$\psi = PR^2 / Ert_m$$

TABLE NB-3685.1-2 CURVED PIPE OR WELDING END ELBOWS, MOMENT LOADING ($\lambda \geq 0.2$)

NB-3686.3 Miter Bends.

The requirements of NB-3681(d) apply.

NB-3686.4 Welding Tee or Branch Connections.

For welding tees (ANSI B16.9) or branch connections (NB-3643) not included in NB-3686.5, the load displacement relationships shall be obtained by assuming that the run pipe and branch pipe extend to the intersection of the run pipe center line with the branch pipe center line. The imaginary juncture is to be assumed rigid, and the imaginary length of branch pipe from the juncture to the run pipe surface is also to be assumed rigid.

[98]

NB-3686.5 Branch Connections in Straight Pipe.

(For branch connections in straight pipe meeting the dimensional limitations of NB-3683.8.) The load displacement relationships may be obtained by modeling the branch connections in the piping system analysis (NB-3672) as shown in (a) through (d) below. (See Fig. NB-3686.5-1.)

(a) The values of k are given below.

For M_{x3} :

$$k = 0.1 (D/T_r)^{1.5} [(T_r/t_n) (d/D)]^{1/2} (T'_b/T_r)$$

For M_{z3} :

$$k = 0.2(D/T_r)[(T_r/t_n)(d/D)]^{1/2}(T'_b/T_r)$$

where

D = run pipe outside diameter, in.

d = branch pipe outside diameter, in.

Page 170

Page 171

E = modulus of elasticity, psi

I_b = moment of inertia of branch pipe, in.⁴ (to be calculated using d and T_b)

M = M_{x3} or M_{z3} , as defined in NB-3683.1(d)

T_r = run pipe wall thickness, in.

ϕ = rotation in direction of moment, rad

IN STRAIGHT PIPE**

FIG. NB-3686.5-1 BRANCH CONNECTIONS IN STRAIGHT PIPE

NB-3690 DIMENSIONAL REQUIREMENTS FOR PIPING PRODUCTS

NB-3691 Standard Piping Products

Dimensions of standard piping products shall comply with the standards and specifications listed in Table NB-3132-1.

However, compliance with these standards does not replace or eliminate the requirements of NB-3625.

NB-3692 Nonstandard Piping Products

The dimensions of nonstandard piping products shall be such as to provide strength and performance as required by this Subsection. Nonstandard piping products shall be designed in accordance with NB-3640.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NB-4000

ARTICLE NB-4000 FABRICATION AND INSTALLATION

Page 173

NB-4100 GENERAL REQUIREMENTS

NB-4110 INTRODUCTION

Components, parts, and appurtenances shall be fabricated and installed in accordance with the requirements of this Article and shall be manufactured from materials which meet the requirements of NB-2000.

NB-4120 CERTIFICATION OF MATERIALS AND FABRICATION BY CERTIFICATE HOLDER

NB-4121 Means of Certification

The Certificate Holder for an item shall certify, by application of the appropriate Code Symbol and completion of the appropriate Data Report in accordance with NCA-8000, that the materials used comply with the requirements of NB-2000 and that the fabrication or installation complies with the requirements of this Article.

NB-4121.1 Certification of Treatments, Tests, and Examinations.

If the Certificate Holder or Subcontractor performs treatments, tests, repairs, or examinations required by other Articles of this Subsection, the Certificate Holder shall certify that this requirement has been fulfilled (NCA-3862). Reports of all required treatments and of the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

NB-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication or installation of the item the material is subjected to heat treatment that has not been covered by treatment of the test coupons (NB-2200) and that may reduce either tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of NB-2000.

NB-4121.3 Repetition of Surface Examination After Machining.

If, during the fabrication or installation of an item, materials for pressure-containing parts are machined, then the Certificate Holder shall reexamine the surface of the material in accordance with NB-2500 when:

(a) the surface was required to be examined by the magnetic particle or liquid penetrant method in accordance with NB-2500; and

(b) the amount of material removed from the surface exceeds the lesser of $\frac{1}{8}$ in. (3.2 mm) or 10% of the minimum required thickness of the part.

NB-4122

NB-4122 Material Identification

(a) Material for pressure-retaining parts shall carry identification markings which will remain distinguishable until the component is assembled or installed. If the original identification markings are cut off or the material is divided, the marks shall either be transferred to the parts cut or a coded marking shall be used to ensure identification of each piece of material during subsequent fabrication or installation. In either case, an as-built sketch or a tabulation of materials shall be made identifying each piece of material with the Certified Material Test Report, where applicable, and the coded marking. For studs, bolts, nuts, and heat exchanger tubes it is permissible to identify the Certified Material Test Reports for material in each component in lieu of identifying each piece of material with the Certified Material Test Report and the coded marking. Material supplied with a Certificate of Compliance, and welding and brazing material, shall be identified and controlled so that they can be traced to each component or installation of a piping system, or else a control procedure shall be employed which ensures that the specified materials are used.

Page 180

(b) Material from which the identification marking is lost shall be treated as non-conforming material until appropriate tests or other verifications are made and documented to assure material identification. Testing is required unless positive identification can be made by other documented evidence. The material may then be re-marked upon establishing positive identification.

NB-4122.1 Marking Material.

Material shall be marked in accordance with NB-2150.

NB-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with requirements of NB-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to NB-5500 and NB-5100, respectively, unless so specified.

NB-4125 Testing of Welding and Brazing Material

All welding and brazing material shall meet the requirements of NB-2400.

NB-4130 REPAIR OF MATERIAL

NB-4131 Elimination and Repair of Defects

Material originally accepted on delivery in which defects exceeding the limits of NB-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used provided the condition is corrected in accordance with the requirements of NB-2500 for the applicable product form, except:

- (a) the limitation on the depth of the weld repair does not apply;
- (b) the time of examination of the weld repairs to weld edge preparations shall be in accordance with NB-5130;
- (c) radiographic examination is not required for weld repairs to seal membrane material when the material thickness is $\frac{1}{4}$ in. (6 mm) or less.

NB-4132 Documentation of Repair Welds of Base Material

The Certificate Holder who makes a repair weld exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, shall prepare a report which shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results of repair welds.

NB-4200 FORMING, FITTING, AND ALIGNING

NB-4210 CUTTING, FORMING, AND BENDING

NB-4211 Cutting

Materials may be cut to shape and size by mechanical means, such as machining, shearing, chipping, or grinding, or by thermal cutting.

NB-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material, using preheat schedules such as suggested in Appendix D.

NB-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend pressure-retaining material (NB-4223), including weld metal, provided the required dimensions are attained (see NB-4214 and NB-4220), and provided the impact properties of the material, when required, are not reduced below the minimum specified values, or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (121°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in NB-4213. When required, the process shall be qualified to meet thickness requirements as outlined in NB-4223.1.

NB-4213 Qualification of Forming Processes for Impact Property Requirements

A procedure qualification test shall be conducted using specimens taken from material of the same specification, grade or class, heat treatment, and with similar impact properties, as required for the material in the component. These specimens shall be subjected to the equivalent forming or bending process and heat treatment as the material in the component.

Applicable tests

Page 181

shall be conducted to determine that the required impact properties of NB-2300 are met after straining.

NB-4213.1 Exemptions.

Procedure qualification tests are not required for materials listed in (a) through (f) below:

(a) hot formed material, such as forgings, in which the hot forming is completed by the Material Organization prior to removal of the impact test specimens;

(b) hot formed material represented by test coupons which have been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;

(c) material which does not require impact tests in accordance with NB-2300;

(d) material which has a final strain less than 0.5%;

(e) material where the final strain is less than that of a previously qualified procedure for that material;

(f) material from which the impact testing is required by NB-2300 is performed on each heat and lot, as applicable, after forming.

NB-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

(a) The tests shall be performed on three different heats of material both before straining and after straining and heat treatment to establish the effects of the forming and subsequent heat treatment operations.

(b) Specimens shall be taken in accordance with the requirements of NB-2000 and shall be taken from the tension side of the strained material.

(c) The percent strain shall be established by the following formulas.

For cylinders:

$$\% \text{ strain} = \frac{50t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For spherical or dished surfaces:

$$\% \text{ strain} = \frac{75t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For pipe:

$$\% \text{ strain} = \frac{100r}{R}$$

where

R	= nominal bending radius to the center line of the pipe, in.
R_f	= final radius to center line of shell, in.
R_o	= original radius (equal to infinity for a flat part), in.
r	= nominal radius of the pipe, in.
t	= nominal thickness, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient C_v test specimens shall be taken from each of the three heats of material to establish a transition curve showing both the upper and lower shelves. On each of the three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen for each shelf. Depending on the product form, it may be necessary to plot the transition curves using both lateral expansion and energy level data (NB-2300). In addition, drop weight tests shall be made when required by NB-2300.

(f) Using the results of the impact test data from each of three heats, taken both before and after straining, determine either:

(1) the maximum change in *NDT* temperature along with:

(a) the maximum change of lateral expansion and energy at the temperature under consideration; or

(b) the maximum change of temperature at the lateral expansion and energy levels under consideration; or

(2) when lateral expansion is the acceptance criterion (NB-2300), either the maximum change in temperature or the maximum change in lateral expansion.

NB-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the component shall have impact properties before forming sufficient to compensate for the maximum loss of impact properties due to the qualified forming processes used.

NB-4213.4 Requalification.

A new procedure qualification test is required when any of the changes in (a), (b), or (c) below are made.

(a) The actual postweld heat treatment time at temperature is greater than previously qualified considering NB-2211. If the material is not postweld heat treated, the procedure must be qualified without postweld heat treatment.

(b) The maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%.

Page 182

FIG. NB-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

FIG. NB-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

(c) Preheat over 250°F (121°C) is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

NB-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of NB-3000, the material may be repaired in accordance with NB-4130.

NB-4220 FORMING TOLERANCES

NB-4221 Tolerance for Vessel Shells

Cylindrical, conical, or spherical shells of a completed vessel, except formed heads covered by NB-4222, shall meet the requirements of the following subparagraphs at all cross sections.

NB-4221.1 Maximum Difference in Cross-Sectional Diameters.

The difference in inches between the maximum and minimum diameters at any cross section shall not exceed the smaller of $(D + 50)/200$ and $D/100$, where D is the nominal inside diameter, in., at the cross section under consideration. The diameters may be measured on the inside or outside of the vessel. If measured on the outside, the diameters shall be corrected for the plate thickness at the cross section under consideration (Fig. NB-4221.1-1). When the cross section passes through an opening, the permissible difference in inside diameters given herein may be increased by 2% of the

inside diameter of the opening.

NB-4221.2 Maximum Deviation From True Theoretical Form for External Pressure.

Vessels designed for external pressure shall meet the tolerances given in (a) through (c) below.

(a) The maximum plus or minus deviation from the true circular form of cylinders or the theoretical form of other shapes, measured radially on the outside or inside of the component, shall not exceed the maximum permissible deviation obtained from Fig. NB-4221.2(a)-1. Measurements shall be made from a segmental circular template having the design inside or outside radius depending on where the measurements are taken and a chord length equal to twice the arc length obtained from Fig. NB-4221.2(a)-2. For Fig. NB-4221.2(a)-1, the maximum permissible deviation e need not be less than $0.3t$. For Fig. NB-4221.2(a)-2, the arc length need not be greater than $0.30D_o$. Measurements shall not be taken on welds or other raised parts.

(b) The value of t , in., at any cross section is the nominal plate thickness less corrosion allowance for sections of constant thickness and the nominal thickness of the thinnest plate less corrosion allowance for sections having plates of more than one thickness.

(c) The value of L in Figs. NB-4221.2(a)-1 and NB-4221.2(a)-2 is determined by (1) through (3) below.

(1) For cylinders, L is as given in NB-3133.2.

(2) For cones, L is the axial length of the conical section if no stiffener rings are used or, if stiffener rings are used, the axial length from the head bend line at the large end of the cone to the first stiffener ring, with D_o taken as the outside diameter in inches of the cylinder at the large end of the cone.

(3) For spheres, L is one-half of the outside diameter D_o , in.

NB-4221.3 Deviations From Tolerances.

Deviations from the tolerance requirements stipulated in NB-4221.1 and NB-4221.2 are permitted, provided the drawings are modified and reconciled with the Design Report (NCA-3551) and provided the modifications are certified by a registered Professional Engineer in an addendum to the Design Report.

NB-4221.4 Tolerance Deviations for Vessel Parts Fabricated From Pipe.

Vessel parts subjected to either internal or external pressure and fabricated from pipe, meeting all other requirements of this Subsection, may have variations of diameter and deviations from circularity permitted by the specification for such pipe.

NB-4222 Tolerances for Formed Vessel Heads

The tolerance for formed vessel heads shall be as set forth in the following subparagraphs.

NB-4222.1 Maximum Difference in Cross-Sectional Diameters.

The skirt or cylindrical end of a formed head shall be circular to the extent that the difference in inches between the maximum and minimum diameters does not exceed the lesser of $(D + 50)/200$ and $(D + 12)/100$,

Page 183

Page 184

FIG. NB-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

FIG. NB-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

where D is the nominal inside diameter, in., and shall match the cylindrical edge of the adjoining part within the

alignment tolerance specified in NB-4232.

FIG. NB-4221.2(a)-2

NB-4222.2 Deviation From Specified Shape

(a) The inner surface of a torispherical or ellipsoidal head shall not deviate outside the specified shape by more than $1\frac{1}{4}\%$ of D , inside the specified shape by more than $\frac{5}{8}\%$ of D , where D is the nominal inside diameter of the vessel. Such deviations shall be measured perpendicular to the specified shape and shall not be abrupt. The knuckle radius shall not be less than specified. For 2:1 ellipsoidal heads, the knuckle radius may be considered to be 17% of the diameter of the vessel.

(b) Hemispherical heads and any spherical portion of a formed head shall meet the local tolerances for spheres as given in NB-4221.2, using L as the outside spherical radius, in., and D_o as two times L .

(c) Deviation measurements shall be taken on the surface of the base material and not on welds.

NB-4223 Tolerances for Formed or Bent Piping

The tolerances for formed or bent piping shall be as set forth in the following subparagraphs.

NB-4223.1 Minimum Wall Thickness

(a) In order to assure that the wall thickness requirements of the design calculations are met, the actual thickness shall be measured, or the process shall be qualified by demonstrating that it will maintain the required wall thickness.

(b) As an alternative to (a) above, the requirements of Table NB-3642.1(b)-1 shall be followed.

NB-4223.2 Ovality Tolerance.

Unless otherwise justified by the Design Report, the ovality of piping after bending shall not exceed 8% as determined by:

$$100 \times (D_{\max} - D_{\min}) / D_o$$

where

D_o = nominal pipe outside diameter, in.

$D_{\min}$ = minimum outside diameter after bending or forming, in.

$D_{\max}$ = maximum outside diameter after bending or forming, in.

NB-4230 FITTING AND ALIGNING

NB-4231 Fitting and Aligning Methods

Parts that are to be joined by welding may be fitted, aligned, and retained in position during the welding operation by the use of bars, jacks, clamps, tack welds, or temporary attachments.

NB-4231.1 Tack Welds.

Tack welds used to secure alignment shall either be removed completely, when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds shall be removed.

NB-4232 Alignment Requirements When Components Are Welded From Two Sides

(a) Alignment of sections which are welded from two sides shall be such that the maximum offset of the finished weld

will not be greater than the applicable amount listed in Table NB-4232-1, where t is the nominal thickness of the thinner section at the joint.

(b) Joints in spherical vessels, joints within heads, and joints between cylindrical shells and hemispherical heads shall meet the requirements in Table NB-4232-1 for longitudinal joints.

NB-4232.1 Fairing of Offsets.

Any offset within the allowable tolerance provided above shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld. In addition, offsets greater than those stated in Table NB-4232-1 are acceptable provided the requirements of NB-3200 are met.

NB-4233 Alignment Requirements When Inside Surfaces Are Inaccessible

(a) When the inside surfaces of items are inaccessible for welding or fairing in accordance with NB-4232, alignment of sections shall meet the requirements of (1) and (2) below:

(1)(a) For circumferential joints the inside diameters shall match each other within $\frac{1}{16}$ in. (1.6 mm). When the items are aligned concentrically, a uniform mismatch of $\frac{1}{32}$ in. (0.8 mm) all around the joint can result as shown in Fig.

NB-4233(a)-1 sketch (a).

Page 186

However, other variables not associated with the diameter of the item often result in alignments that are offset rather than concentric. In these cases, the maximum misalignment at any one point around the joint shall not exceed $\frac{3}{32}$ in. (2.4 mm) as shown in Fig. NB-4233(a)-1 sketch (b). Should tolerances on diameter, wall thickness, out-of-roundness, etc., result in inside diameter variations which do not meet these limits, the inside diameters shall be counterbored, sized, or ground to produce a bore within these limits, provided the requirements of NB-4250 are met.

**TABLE NB-4232-1
MAXIMUM ALLOWABLE OFFSET IN
FINAL WELDED JOINTS**

Section Thickness, in.	Direction of Joints	
	Longitudinal	Circumferential
Up to $\frac{1}{2}$, incl.	$\frac{1}{4}t$	$\frac{1}{4}t$
Over $\frac{1}{2}$ to $\frac{3}{4}$, incl.	$\frac{1}{8}$ in.	$\frac{1}{4}t$
Over $\frac{3}{4}$ to $1\frac{1}{2}$, incl.	$\frac{1}{8}$ in.	$\frac{3}{16}$ in.
Over $1\frac{1}{2}$ to 2, incl.	$\frac{1}{8}$ in.	$\frac{1}{8}t$
Over 2	Lesser of $\frac{1}{16}t$ or $\frac{3}{8}$ in.	Lesser of $\frac{1}{8}t$ or $\frac{3}{4}$ in.

TABLE NB-4232-1 MAXIMUM ALLOWABLE OFFSET IN FINAL WELDED JOINTS

(b) Offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(2) For longitudinal joints the misalignment of inside surfaces shall not exceed $\frac{3}{32}$ in. (2.4 mm) and the offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(b) Single welded joints may meet the alignment requirements of (a)(1) and (a)(2) above in lieu of the requirements of NB-4232.

NB-4240 REQUIREMENTS FOR WELD JOINTS IN COMPONENTS

NB-4241 Category A Weld Joints in Vessels and Longitudinal Weld Joints in Other Components

Category A weld joints in vessels and longitudinal weld joints in other components shall be full penetration butt joints. Joints that have been welded from one side with backing that has been removed and those welded from one side without backing are acceptable as full penetration welds provided the weld root side of the joints meets the requirements of NB-4424.

NB-4242 Category B Weld Joints in Vessels and Circumferential Weld Joints in Other Components

Category B weld joints in vessels and circumferential weld joints in other components shall be full penetration butt joints, except that piping 2 in. nominal pipe size (DN 50) and smaller may be socket welded. When used, backing strips shall be continuous in cross section. Joints prepared with opposing lips to form an integral backing strip and joints with backing strips which are not later removed are acceptable provided the requirements of NB-3352.2 are met.

NB-4243 Category C Weld Joints in Vessels and Similar Weld Joints in Other Components

Category C weld joints in vessels and similar weld joints in other components shall be full penetration joints, except that 2 in. nominal pipe size (DN 50) and smaller socket welded joints may be used on component nozzles and in piping. Joints that have been welded from one side with backing that has been removed and those welded from one side without backing are acceptable as full penetration welds provided the weld root side of the joints meets the requirements of NB-4424. Either a butt welded joint or a full penetration corner joint as shown in Fig. NB-4243-1 shall be used.

NB-4244 Category D Weld Joints in Vessels and Branch Piping Weld Joints in Other Components

Category D weld joints in vessels and similar weld joints in other components shall be full or partial penetration weld joints using one of the details of (a) through (e) below.

(a) *Butt Welded Nozzles and Branch Piping Connections.* Nozzles and branch piping connections shall be attached by full penetration butt welds through the wall of the component, nozzle, or branch as shown in Fig. NB-4244(a)-1. Backing strips, if used, shall be removed.

(b) *Corner Welded Nozzles and Branch Piping Connections.* Nozzles and branch piping connections shall be joined to the component by full penetration welds through the wall of the component, nozzle, or branch similar to those shown in Fig. NB-4244(b)-1. Backing strips, if used, shall be removed.

(c) *Deposited Weld Metal of Openings for Nozzles and Branch Piping Connections.* Nozzles and branch piping connections shall be joined to the component

Page 187

Page 188

GENERAL NOTE:

The weld end transitions are typical and are not intended as requirements. Refer to NB-4250 for weld end transition requirements.

FIG. NB-4233(a)-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

FIG. NB-4243-1 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS (NB-3352.3)

FIG. NB-4243-1 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS (NB-3352.3)

Page 190

GENERAL NOTES:

- (a) For definitions of symbols, see NB-3352.4(a) for vessels and NB-3643 for piping.
- (b) Reinforcement may be distributed within the limits prescribed by the Code.

FIG. NB-4244(a)-1 NOZZLE, BRANCH, AND PIPING CONNECTIONS JOINED BY FULL PENETRATION BUTT WELDS

FIG. NB-4244(a)-1 NOZZLE, BRANCH, AND PIPING CONNECTIONS JOINED BY FULL PENETRATION BUTT WELDS

by full penetration weld to built-up weld deposits applied to the component, nozzle, or branch as shown in Fig. NB-4244(c)-1. Backing strips, if used, shall be removed. Fillet welds shall be used only to provide a transition between the parts joined or to provide a seal. The fillet welds, when used, shall be finished by grinding to provide a smooth surface having a transition radius at its intersection with either part being joined.

GENERAL NOTE: For definitions of symbols, see NB-3352.4(b) for vessels and NB-3643 for piping.

FIG. NB-4244(b)-1 NOZZLE, BRANCH, AND PIPING CONNECTIONS JOINED BY FULL PENETRATION CORNER WELDS

FIG. NB-4244(b)-1 NOZZLE, BRANCH, AND PIPING CONNECTIONS JOINED BY FULL PENETRATION CORNER WELDS

(d) *Partial Penetration Welded Nozzles and Branch Piping Connections.* Partial penetration welds in components and branch piping connections shall meet the weld design requirements of NB-3352.4(d) for vessels or NB-3643 for piping branch connections. Nozzles shall be attached as shown in Figs. NB-4244(d)-1 and NB-4244(d)-2.

(e) *Oblique Nozzles and Branch Piping Connections.* Oblique nozzles and branch piping connections shall be joined to the component by full penetration welds through the nozzle or branch as shown in Fig. NB-4244(e)-1. Backing rings, if used, shall be removed.

NB-4250 WELDING END TRANSITIONS - MAXIMUM ENVELOPE

The welding ends of items shall provide a gradual change in thickness from the item to the adjoining item. Any welding end transition which lies entirely within the envelope shown in Fig. NB-4250-1 is acceptable provided:

- (a) the wall thickness in the transition region is not less than the minimum wall thickness of the adjoining pipe;
- (b) sharp reentrant angles and abrupt changes in slope in the transition region are avoided. When the included angle between any two adjoining surfaces of a taper transition is less than 150 deg., the intersection or corner (except for the weld reinforcement) shall be provided with a radius of at least $0.05t_{\min}$; and
- (c) if the weld is subject to preservice inspection, the length of the counterbore shall be $2t_{\min}$ for pipe and $t_{\min}$ for components and fittings, as shown in Fig. NB-4250-2 or Fig. NB-4250-3.

NB-4300 WELDING QUALIFICATIONS

NB-4310 GENERAL REQUIREMENTS

NB-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure qualification requirements of Section IX and this Subsection may be used for welding pressure-retaining material or attachments thereto. Any process used shall be such that the records required by NB-4320 can be prepared, except that records for stud welds shall be traceable to the welders and welding operators and not necessarily to each specific weld.

NB-4311.1 Stud Welding Restrictions.

Stud welding is acceptable only for nonstructural and temporary attachments (NB-4435). Studs shall be limited to 1 in. (25 mm) maximum diameter for round studs and an equivalent cross-sectional area for studs of other shapes when welding in the flat position and $\frac{3}{4}$ in. (19 mm) diameter for all other welding positions. Postweld heat treatment shall comply with NB-4600, except that time at temperature need not exceed $\frac{1}{2}$ hr regardless of base material thickness. Welding procedure and performance qualification shall comply with the requirements of Section IX.

NB-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided:

- (a) temporary attachments are removed in accordance with the provisions of NB-4435(b); and
- (b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec, and the minimum thickness of the material to which the attachment is made is greater than 0.09 in. (2.9 mm); and
- (c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

NB-4311.4 Inertia and Continuous Drive Friction Welding

- (a) Inertia and continuous drive friction welding shall not be used for the fabrication of vessels and piping.
- (b) The weld between the two members shall be a full penetration weld.

NB-4320 WELDING QUALIFICATIONS, RECORDS, AND IDENTIFYING STAMPS

NB-4321 Required Qualifications

(a) Each Certificate Holder is responsible for the welding done by his organization, and each Certificate Holder shall establish the procedure and conduct the tests required by this Article and by Section IX in

Page 192

Page 193

GENERAL NOTE: For definitions of symbols, see NB-3352.4(c) for vessels and NB-3643 for piping.

FIG. NB-4244(c)-1 DEPOSITED WELD METAL USED AS REINFORCEMENT OF OPENINGS FOR NOZZLE, BRANCH, AND PIPING CONNECTIONS

GENERAL NOTES:

- Weld deposit reinforcement, if used, shall be examined as required in NB-5244.
- The $3/4 t_n$ min. dimension applies to the fillet leg and the J-groove depth.
- Weld groove design for oblique nozzles of this type requires special consideration to achieve the $1.25 t_n$ minimum depth of weld and adequate access for welding inspection. With due regard to the requirements in Fig. NB-4244(c)-1, the welds shown in the sketches may be on either the inside or the outside. Weld preparation may be J-groove as shown or straight bevel. If weld deposit reinforcement is not used, r_1 shall apply to I.D. of base material instead of I.D. of weld buildup.
- For definitions of symbols, see NB-3352.4(d) for vessels and NB-3643 for piping.

FIG. NB-4244(d)-1 PARTIAL PENETRATION NOZZLE AND BRANCH PIPING CONNECTIONS

FIG. NB-4244(d)-1 PARTIAL PENETRATION NOZZLE AND BRANCH PIPING CONNECTIONS

FIG. NB-4244(d)-2 PARTIAL PENETRATION NOZZLE FOR COAXIAL CYLINDERS

FIG. NB-4244(d)-2 PARTIAL PENETRATION NOZZLE FOR COAXIAL CYLINDERS

order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures.

GENERAL NOTES:

(a) Step 1 examination required before assembly.

(b) For definitions of symbols, see NB-3352.4(e) for vessels and NB-3643 for piping.

FIG. NB-4244(e)-1 OBLIQUE CONNECTIONS

FIG. NB-4244(e)-1 OBLIQUE CONNECTIONS

(b) Procedures, welders, and welding operators used to join permanent or temporary attachments to pressure parts and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.

(c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.

(d) NCA-3131 provides specific additional requirements when welding services are subcontracted to or through organizations not holding an appropriate Certificate of Accreditation.

NB-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of the qualified welding procedures and of the welders and welding operators qualified by him, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

Page 196

Page 197

GENERAL NOTES:

- (a) Weld bevel is shown for illustration only
- (b) The weld reinforcement permitted by NC-4426 may lie outside the maximum envelope.

NOTES:

- (1) The value of t_{min} is whichever of the following is applicable:
 - (a) the minimum ordered wall thickness of the pipe;
 - (b) 0.875 times the nominal wall thickness of pipe ordered to a pipe schedule wall thickness which has an under tolerance of 12.5%;
 - (c) the minimum ordered wall thickness of the cylindrical welding end of a component or fitting (or the thinner of the two) when the joint is between two components.
- (2) The maximum thickness at the end of the component is:
 - (a) the greater of $t_{min} + 0.15$ in. or $1.15t_{min}$ when ordered on a minimum wall basis;
 - (b) the greater of $t_{min} + 0.15$ in. or $1.0t_{nom}$ when ordered on a nominal wall basis.

FIG. NB-4250-1 WELDING END TRANSITIONS - MAXIMUM ENVELOPE

FIG. NB-4250-2 COMPONENT TO PIPE WELD

FIG. NB-4250-2 COMPONENT TO PIPE WELD

FIG. NB-4250-3 PIPE TO PIPE WELD

FIG. NB-4250-3 PIPE TO PIPE WELD

NB-4322.1 Identification of Joints by Welder or Welding Operator

(a) Each welder or welding operator shall apply the identification mark assigned by the Certificate Holder on or adjacent to all permanent welded joints or series of joints on which he welds. The marking shall be at intervals of 3 ft (0.9 m) or less and shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in each item and of the welders and welding operators used in making each of the joints.

(b) When a multiple number of permanent structural attachment welds, nonstructural welds, fillet welds, socket welds, welds of specially designed seals, weld metal cladding, hard surfacing, and tube-to-tubesheet welds are made on an item, the Certificate Holder need not identify the welder or welding operator who welded each individual joint, provided:

(1) the Certificate Holder maintains a system that will identify the welders or welding operators who made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;

(2) the welds in each category are all of the same type and configuration and are welded with the same Welding Procedure Specification.

(c) The identification of welder or welding operator is not required for tack welds.

NB-4323 Welding Prior to Qualifications

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with NB-4320 and Section IX shall be used.

NB-4324 Transferring Qualifications

The welding procedure qualifications and the performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures and shall not qualify welders or welding operators to weld for any other Certificate Holder, except as provided in Section IX, QW-201 and QW-300.2.

NB-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

NB-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented or modified by the requirements of this Article.

NB-4333 Heat Treatment of Qualification Welds for Ferritic Materials

Postweld heat treatment of procedure qualification welds shall conform to the applicable requirements of NB-4620 and Section IX. The postweld heat treatment time at temperature shall be at least 80% of the maximum time to be applied to the component weld material. The postweld heat treatment total time may be applied in one heating cycle.

NB-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test specimens. When each process cannot be included in the full-size impact test specimen at the $\frac{1}{4}t$ location required by this Section, additional full-size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full-size test specimens. As an alternative, additional test welds can be made with each process so that full-size specimens can be tested for each process.

NB-4334.1 Coupons Representing the Weld Deposit.

Impact test specimens and testing methods shall conform to NB-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $0.25t$ and, where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in NB-4620 and the test assembly is cooled at an accelerated rate, the

Page 199

longitudinal axis of the specimen shall be a minimum of t from the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld. Where drop weight specimens are required, the tension surface of the specimen shall be oriented parallel to the surface of the test weld assembly.

NB-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by NB-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be oriented in the direction parallel to the principal direction of rolling or forging.

(b) The heat affected zone impact test specimens and testing methods shall conform to the requirements of NB-2321.2. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V-notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may be inclined to allow the root of the notch to align parallel to the fusion line. When a grain refining heat treatment is not performed on welds made by the electroslog or electrogas welding process, the notch for the impact specimens shall be located in the grain coarsened region.

(c) For the comparison of heat affected zone values with base material values [NB-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material. When required by NB-4335.2(b)(1), drop-weight specimens shall be removed from a depth as near as practical to midway between the surface and center thickness of the unaffected base material and shall be tested in accordance with the requirements of NB-2321.1.

NB-4335 Impact Test Requirements

When materials are required to be impact tested per NB-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. The weld procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of NB-2330 and NB-4334. Retests in accordance with the provisions of NB-2350 are permitted.

NB-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. (16 mm) in thickness when the weld will be made on the surface or penetrate base material that requires impact testing in accordance with NB-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with NB-2310, regardless of the depth of the repair.

(b) The impact test requirements and acceptance standards for welding procedure qualification weld metal shall be the same as specified in NB-2330 for the base material to be welded or repaired. Where two materials are to be joined by welding and have different fracture toughness requirements, the test requirements and acceptance standards of either material may be used for the weld metal except where this is otherwise specified by NCA-1280 or other parts of this

Subsection.

NB-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. (16 mm) and either of the base materials require impact testing in accordance with the rules of NB-2310. The only exceptions to the requirements are the following:

- (1) the qualification for welds in P-Nos. 1 and 3 and SA-336 F12 materials that are postweld heat treated and are made by any process other than electroslog, electrogas, or thermit;
- (2) the qualification for weld deposit cladding or hard-facing on any base material.

(b) Impact testing of the welding procedure qualification test heat affected zone, where required by this paragraph, shall be conducted in accordance with (b)(1) through (b)(3), or (b)(4) through (b)(6), and (c), if applicable.

- (1) For tests of welding procedure qualifications for material that requires testing in accordance with NB-2331 and NB-2332(b), the T_{NDT} of the unaffected

Page 200

base material shall be determined to establish the test temperature for the Charpy V-notch tests. The Charpy V-notch specimens representing the heat affected zone material and the unaffected base material shall be tested at the ($T_{NDT} + 60^{\circ}\text{F}$) temperature of the unaffected base material. The Charpy V-notch impact tests of the unaffected base material shall meet the requirements of NB-2331(a). If the average lateral expansion values of the three HAZ specimens are equal to or greater than the average value for the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable, and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(2) If the average Charpy V-notch lateral expansion for the heat affected zone of (b)(1) above is less than that for the unaffected base material, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data shall then be obtained as specified in (b)(3) below to provide an additive temperature for any base material for which the welding procedure is being qualified, and shall be included. Alternatively, the welding procedure qualification may be rewelded and retested.

(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification heat affected zone or the unaffected base material, or both, at temperatures which provide lateral expansion values equal to or greater than 35 mils (0.89 mm). The average lateral expansion data for the heat affected zone and the unaffected base material shall be plotted on a lateral expansion-temperature chart. The temperatures at which these two sets of data exhibit a common lateral expansion value equal to or greater than 35 mils shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference shall be used in (b)(2) above as the adjustment temperature. The adjustment temperature shall be added to the highest RT_{NDT} temperature established by the tests of NB-2331 and NB-2332(b) for all of the base material to be welded by this procedure in production. If the temperature difference is zero or is a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NB-2331 and NB-2332(b) will still apply as stated in (b)(1) above. Where the actual RT_{NDT} is not required for the production material to be welded, for example, where a testing temperature is established by the Design Specification to determine that the RT_{NDT} is at or below the specified temperature, the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(4) For tests of welding procedure qualifications for materials that require tests in accordance with NB-2332(a), the three Charpy V-notch heat affected zones and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with NB-2332(a)(1). The Charpy V-notch impact test of the unaffected base material shall meet the requirements of Table NB-2332-1. If the average lateral expansion values of the three HAZ specimens are equal to or greater than the average value of the unaffected base material Charpy V-notch specimens, the test shall be considered acceptable, and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(5) If the heat affected zone Charpy V-notch average lateral expansion values of (b)(4) above are less than the unaffected base material and the welding procedure qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data shall then be obtained as specified in (b)(6) below to provide an additive temperature for the adjustment of the lowest service temperature of the base material that is to be welded in production with the welding procedure that is being qualified. Alternatively, the welding procedure qualification may be rewelded and retested.

(6) The data for use in (b)(5) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification heat affected zone or the unaffected base material, or both, at temperatures which provide lateral expansion values that meet or exceed those required for the thickness of the material to be welded in production (Table NB-2332-1). The average lateral expansion data for the heat affected zone and unaffected base material shall be plotted on a lateral expansion-temperature chart. The temperatures at which these two sets of data exhibit a common acceptable value of lateral expansion for the production thickness involved shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(5) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the

Page 201

highest Lowest Service Temperature established by the tests of NB-2332 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NB-2332 will still apply as stated in (b)(4) above.

Where the actual Lowest Service Temperature is not required for the product material to be welded, for example where a testing temperature is established by specification to determine that the material has adequate lateral expansion to meet the requirements of Table NB-2332-1 at the specified test temperature, the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material upon which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) or (b)(4) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact specimens of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average lateral expansion of the heat affected zone relative to the average lateral expansion of the unaffected base material shall be followed as in (b)(1) through (b)(3) or (b)(4) through (b)(6) above, as applicable, to determine the data which are to be recorded on the Welding Procedure Qualification Record.

NB-4336 Qualification Requirements for Built-Up Weld Deposits

Built-up weld deposits for base metal reinforcement shall be qualified in accordance with the requirements of NB-4331 through NB-4335.

NB-4350 SPECIAL QUALIFICATION REQUIREMENTS FOR TUBE-TO-TUBESHEET WELDS

NB-4351 General Requirements

The welding procedure for tube-to-tubesheet welds shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed below are made in the procedure. Changes other than those so given may be made in a procedure without the necessity for requalification, provided the procedure specification is amended to show these changes.

NB-4352 Essential Variables for All Welding Processes

Essential variables for all welding processes shall be as listed in (a) through (k) below:

- (a) a change from one welding process to any other welding process or combination of welding processes;
- (b) a change in the P-Number classification of tube material in Section IX, QW-422; separate qualification is required for each tube material which is not included under any P-Number;
- (c) a change in the P-Number of the tubesheet base material. The base material may be a homogeneous material or a cladding material of wrought type or weld overlay type. If welding is performed between the tube and cladding, the cladding shall be considered the base material. A separate qualification is required for welding tubes to base material or cladding material which is not included under any P-Number;
- (d) changes in the weld metal analysis of the deposited weld metal as given in (1) and (2) below:
 - (1) a change from any A-Number in Section IX, QW-442, to any other A-Number or to any F-Number in QW-432 or to any analysis not listed in the tables, except that each AISI type similar to A-No. 7 or A-No. 8 of QW-442 shall require separate qualifications;
 - (2) a change from any F-Number in QW-432 to any other F-Number or to any A-Number in QW-442 or to any analysis not listed in the tables;
- (e) for tubes of specified wall thicknesses of 0.100 in. (2.54 mm) or less, an increase or decrease of 10% of specified wall thickness or specified diameter;
- (f) for specified wall thicknesses greater than 0.100 in. (2.54 mm), only one qualification test is required;
- (g) a decrease of 10% or more in the specified width of the ligament between tube holes when the specified width of the ligament is less than the greater of $\frac{3}{8}$ in. (10 mm) or three times the specified tube wall thickness;
- (h) the addition of other welding positions than those already qualified (Section IX, QW-461.1);
- (i) a change in the specified preheating temperature range;
- (j) a change in the specified postweld heat treating temperature;
- (k) a change from multiple pass to single pass or vice versa.

NB-4353 Essential Variables for Shielded Metal-Arc Welding

An additional essential variable for shielded metal-arc welding is an increase in electrode diameter.

NB-4354 Essential Variables for Gas Tungsten-Arc and Gas Metal-Arc Welding

Additional essential variables for gas tungsten-arc and gas metal-arc welding are as given in (a) through (f) below:

- (a) a change in the configuration of the tube sheet at the tube hole edges, including the addition or omission of preplaced metal inserts;
- (b) a change in the size or shape of preplaced metal inserts;
- (c) a change from one shielding gas to another shielding gas or to a mixture of shielding gases;
- (d) when using mixed shielding gas, a change of plus or minus 25% or 5 cu ft/hr (0.14 m³/hr), whichever is the larger, in the rate of flow of the minor gas constituent;
- (e) for gas tungsten-arc welding process, the addition or omission of filler metal;
- (f) a change in the nominal diameter of the filler metal.

NB-4355 Essential Variables for Explosive Welding

Additional essential variables for explosive welding are as given in (a) through (e) below:

- (a) an increase or decrease in the specified tube wall thickness or diameter of 10% for all diameters and wall thicknesses

instead of the provision of NB-4352(e);

- (b) a change in the method of pressure application;
- (c) a change in the type of explosive or a change in energy content of $\pm 10\%$;
- (d) a change of $\pm 10\%$ in the placement of the charge from the tubesheet face;
- (e) a change in the specified clearance between the tube and the tubesheet of $\pm 10\%$.

NB-4356 Test Assembly

The procedure qualification shall be made on a test assembly which simulates the conditions to be used in production with respect to the tube hole pattern and the essential variables listed in NB-4351. In addition, the thickness of the tubesheet in the test assembly shall be as thick as the production tubesheet, except it need not exceed 2 in. (51 mm). The minimum required number of weld joints shall be 10.

NB-4357 Examination of Test Assembly

The assembly shall be examined by a liquid penetrant method in accordance with the requirements of NB-5110 and shall meet the acceptance standards of NB-5350. Following this, the assembly shall be sectioned longitudinally through each tube. The thickness of the assembly may be reduced to $\frac{1}{2}$ in. (13 mm) prior to this sectioning. The four faces of each tube exposed by sectioning shall be polished and etched with a suitable etchant, and shall be visually examined for cracks. The weld throat, minimum leakage path, shall be not less than two-thirds of the specified tube wall thickness, and the weld shall be free from cracks on visual examination with $\times 10$ magnification.

NB-4358 Performance Qualification

NB-4358.1 Welders.

The requirements for the performance qualification test for welders shall be the same as those for the procedure qualification, except that the minimum required number of tubes in the test assembly shall be six.

NB-4358.2 Welding Operators.

The requirements for the performance qualification test for welding operators (automatic weld process) shall be the same as those for the procedure qualification except that:

- (a) the essential variables for performance qualification are those detailed in NB-4352(a), (b), (c), (d), and (h), and
- (b) the minimum required number of tubes in the test assembly shall be six.

NB-4360 QUALIFICATION REQUIREMENTS FOR WELDING SPECIALLY DESIGNED WELDED SEALS

NB-4361 General Requirements

(a) Specially designed welded seals are defined as the walls or membranes, such as an omega shaped seal membrane, which confine the fluid and where strength is provided by a separate device.

(b) The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the essential variables specified or listed in the following paragraphs are made in the procedure. Changes other than those so given may be made in the procedure without the necessity for

Page 203

requalification provided the procedure is amended to show these changes. In addition, the essential variables specified in Section IX shall apply for both procedure and performance qualification.

NB-4362 Essential Variables for Automatic, Machine, and Semiautomatic Welding

The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed in this paragraph or the applicable portions of Section IX are made:

- (a) when preplaced filler metal is melted to form all or part of a weld, a change from one alloy type or classification to any other alloy type or classification of base material or filler metal, even though previously qualified base materials and filler metals are of the same P-Number or A-Number;
- (b) a change of any dimension of the weld joint for automatic or machine welding or a change of any dimension of the weld joint by more than 10% for semiautomatic welding beyond that qualified;
- (c) a change in the nominal size or shape of any filler metal added to the arc;
- (d) for automatic welding, an increase or decrease in the length of the seal weld by more than 30%;
- (e) for automatic welding, a change in the welding current greater than 50% of the difference between the maximum and minimum amperages used during qualification; only two test assemblies need to be welded for requalification;
- (f) any change in the angular relationship or distance between the welding electrode and the work and the filler metal beyond the range qualified;
- (g) the addition or deletion of the use of tack welds or locating fixtures to facilitate alignment or to maintain the root opening of the weld joint;
- (h) the addition or deletion of consumable inserts.

NB-4363 Essential Variables for Manual Welding

The welding procedure must be qualified as a new procedure specification and shall be completely requalified when any of the changes listed in (a) and (b) below are made in the procedure:

- (a) a change of more than $\pm 10\%$ of any dimension of the weld joint cross section other than the included angle of the groove, except that base material thickness may vary from minus 10% to 2.5 times the thickness qualified when welding parts of the same material thickness, or the thin member may vary from minus 10% to 2 times the thickness qualified when welding a thin seal membrane to a thick member;
- (b) when preplaced filler metal is melted to form all or part of a weld, a change from one alloy type or classification to any other alloy type or classification of base material or filler metal, even though previously qualified base materials and filler metals are of the same P-Number or A-Number.

NB-4366 Test Assembly

The test assembly shall consist of a duplicate of the production weld except that tolerances as stated in NB-4362(b) or NB-4363(a) are permitted. Except for automatic welding, the Certificate Holder may use a 12 in. (305 mm) length to qualify, if the length of the production weld is considered to be greater than necessary to qualify.

NB-4366.1 Automatic Welding.

For automatic welding, at least six consecutive test assemblies representing the range of dimensions to be qualified shall be required to establish the reproducibility of the welding procedure. In addition, the Certificate Holder making the production welds shall verify this capability of making two consecutive test assemblies prior to production welding using the previously qualified procedure.

NB-4366.2 Manual, Machine, and Semiautomatic Welding.

For manual, machine, and semiautomatic welding, two test assemblies shall be required.

NB-4367 Examination of Test Assembly

- (a) Where 100% weld penetration is required, the test assembly shall be sectioned, if necessary, to permit examination of the entire underside weld surface.

(b) A minimum of four cross sections shall be taken from each test assembly. One cross section shall be made in a weld start and stop area and the others shall be taken at random. Each cross section shall be examined at $\times 10$ to $\times 15$ magnification in accordance with ASTM Standard E2. All surfaces shall be free of cracks, incomplete penetration, incomplete melting of insert on consumable type welds, and porosity or inclusions in excess of one rounded void with the maximum dimension not greater than 10% of the thickness of the weld. When doubt exists as to the acceptability of the weld, after examination of four cross sections, the Inspector may require that additional metallographic cross sections be prepared for examination of the weld and adjacent base material.

Page 204

NB-4368 Performance Qualification Test

The performance qualification test assembly shall meet the same requirements specified for the procedure qualification test assembly in NB-4366 and shall be examined in accordance with NB-4367. Furthermore, welding operators shall qualify using the welding machine which will be used to make production welds and shall be required to set up the machine with regard to adjustments and settings which affect the welding characteristics. One test assembly is required.

NB-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

NB-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

NB-4411 Identification, Storage, and Handling of Welding Material

Each Certificate Holder is responsible for control of the welding electrodes and other material which is used in the fabrication and installation of components (NB-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

NB-4412 Cleanliness and Protection of Welding Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

NB-4420 RULES FOR MAKING WELDED JOINTS

NB-4421 Backing Rings

When used in components other than piping, backing rings shall conform to the requirements of NB-4240. Backing rings shall not be used in piping unless removed after welding and the inside surfaces of the roots are examined by a magnetic particle or liquid penetrant method, in accordance with NB-5110, and meeting the acceptance standards of NB-5340 or NB-5350. The material for backing rings, when used, shall be compatible with the base metal. Permanent backing rings, when permitted by NB-3352, shall be continuous, and any splices shall be made by full penetration welds. Spacer pins shall not be incorporated into the welds.

NB-4422 Peening

Controlled peening may be performed to minimize distortion. Peening shall not be used on the initial layer, root of the weld metal, or on the final layer unless the weld is postweld heat treated.

NB-4423 Miscellaneous Welding Requirements

(a) Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods, such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetration are otherwise obtained and demonstrated to be satisfactory by welding procedure qualification.

(b) If the welding is stopped for any reason, extra care shall be taken in restarting to get the required penetration and fusion. For submerged arc welding, chipping out a groove in the crater is recommended.

(c) Where single welded joints are used, particular care shall be taken in aligning and separating the components to be joined so that there will be complete penetration and fusion at the bottom of the joint for its full length.

NB-4424 Surfaces of Welds

NB-4424.1 General.

As-welded surfaces are permitted, except for inertia and continuous drive friction welding where the flash shall be removed to sound metal. For piping, the appropriate stress indices given in Table NB-3681(a)-1 shall be applied. However, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, and abrupt ridges and valleys to meet (a) through (f) below.

(a) The surface condition of the finished weld shall be suitable for the proper interpretation of radiographic and other required nondestructive examinations of the weld. In those cases where there is a question regarding the surface condition of the weld on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Reinforcements are permitted in accordance with NB-4426.1 for vessels, pumps, and valves, and NB-4426.2 for piping only for those welds that do not require preservice examination.

Page 205

(c) Undercuts shall not exceed $\frac{1}{32}$ in. (0.8 mm) and shall not encroach on the required section thickness.

(d) Concavity on the root side of a single-welded circumferential butt weld is permitted when the resulting thickness of the weld meets the requirements of NB-3000.

(e) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the required thickness.

(f) Diametrical weld shrinkage is permissible provided an acceptable ultrasonic examination can be performed.

NB-4424.2 Preservice Examination

(a) The surface finish shall be 6.3 Ra or better for a distance of at least $2t^1$ plus 4 in. or 6 in., whichever is greater (Fig. NB-4250-2 or Fig. NB-4250-3), from the edge of the weld crown on at least one side of the weld where an ultrasonic examination is required.

(b) Provide welds a circumferential clearance distance of 15 in. (minimum) for long seam welds. This measurement shall be from the toe of the weld.

(c) A reference system shall be established for all piping and vessel welds subject to surface or volumetric examination.

(1) For piping, each side of each weld joint shall be permanently marked at a minimum of two points in suitable increments from the edge prep. These marks shall be repeated at 90 deg. intervals around the pipe. For welds joining pipes to components, other than vessels where punching is not feasible, punching on the pipe side only is permitted.

(2) For vessels, each side of each weld joint shall be permanently marked at a minimum of two points in suitable increments from the edge prep. These marks shall be repeated along the weld length at 1 ft (0.3 m) intervals for vessel to nozzle welds, and at 3 ft (0.9 m) intervals for all other vessel welds that are subject to preservice examination.

NB-4425 Welding Items of Different Diameters

When items of different diameters are welded together, there shall be a gradual transition between the two surfaces in accordance with NB-4250, unless greater slopes are shown to be acceptable by analysis in accordance with NB-3200. The length of the transition may include the weld.

l equals nominal wall thickness.

NB-4426 Reinforcement of Welds

NB-4426.1 Thickness of Weld Reinforcement for Vessels, Pumps, and Valves.

The surface of the reinforcement of all butt welded joints in vessels, pumps, and valves may be flush with the base material or may have uniform crowns. The height of reinforcement on each face of the weld shall not exceed the thickness in the following tabulation.

Nominal Thickness, in.	Maximum Reinforcement, in.
Up to 1, incl.	$\frac{3}{32}$
Over 1 to 2, incl.	$\frac{1}{8}$
Over 2 to 3, incl.	$\frac{5}{32}$
Over 3 to 4, incl.	$\frac{7}{32}$
Over 4 to 5, incl.	$\frac{1}{4}$
Over 5	$\frac{5}{16}$

NB-4426.2 Thickness of Weld Reinforcement for Piping.

For double-welded butt joints, the limitation on the reinforcement given in Column 1 of the following tabulation shall apply separately to both inside and outside surfaces of the joint. For single-welded butt joints, the reinforcement given in Column 2 shall apply to the inside surface and the reinforcement given in Column 1 shall apply to the outside surface. The reinforcement shall be determined from the higher of the abutting surfaces involved.

Material Nominal Thickness, in.	Column 1	Maximum Reinforcement Thickness, in. Column 2
Up to $\frac{1}{8}$ incl.	$\frac{3}{32}$	$\frac{3}{32}$
Over $\frac{1}{8}$ to $\frac{3}{16}$ incl.	$\frac{1}{8}$	$\frac{3}{32}$
Over $\frac{3}{16}$ to $\frac{1}{2}$ incl.	$\frac{5}{32}$	$\frac{1}{8}$
Over $\frac{1}{2}$ to 1, incl.	$\frac{3}{16}$	$\frac{5}{32}$
Over 1 to 2, incl.	$\frac{1}{4}$	$\frac{5}{32}$
Over 2	Greater of $\frac{1}{4}$ in. or $\frac{1}{8}$ times the width of the weld, in inches	$\frac{5}{32}$

NB-4427 Shape and Size of Fillet Welds

Fillet welds may vary from convex to concave. The shape and size of the weld shall be in accordance with the requirements of Fig. NB-4427-1. A fillet weld in any single continuous weld may be less than the specified fillet weld dimension by not more than $\frac{1}{16}$

Page 206

in. (1.6 mm), provided that the total undersize portion of the weld does not exceed 10% of the length of the weld. Individual undersize weld portions shall not exceed 2 in. (51 mm) in length. In making socket welds, a gap as shown in Fig. NB-4427-1 shall be provided prior to welding. The gap need not be present nor be verified after welding.

NB-4428 Seal Welds of Threaded Joints

Where seal welding of threaded pipe joints is performed, the exposed threads shall be either removed entirely or covered with weld metal.

NB-4429 Welding of Clad Parts²

The joint types and welding procedures used for cladding shall be such as to prevent the formation of brittle weld composition.

NB-4430 WELDING OF ATTACHMENTS

NB-4431 Materials for Attachments

Nonpressure-retaining attachments (NB-1132.1) welded to pressure-retaining components shall be of materials which meet the requirements of NB-2190. Materials for pressure-retaining attachments shall meet the requirements of NB-2120.

NB-4432 Welding of Structural Attachments

The rules of NB-4321 governing welding qualifications shall apply to the welding of structural attachments to pressure-retaining material.

2 Welds that are exposed to corrosive action should have a resistance to corrosion that is not substantially less than that of the cladding. The use of filler metal that weld metal which is similar to the composition of the cladding material is recommended. If weld metal of different composition is used, it should have properties compatible with the application.

NB-4433 Structural Attachments

Structural attachments shall conform reasonably to the curvature of the surface to which they are to be attached and shall be attached by full penetration, fillet, or partial penetration continuous welds. When fillet and partial penetration welds are used on components, the requirements of NB-3123.2 shall be met. Attachments to the internal surfaces of reactor vessels shall be made only with full penetration welds. Figure NB-4433-1 illustrates some of the typical details for attaching structural attachments to a component using full penetration welds. Valve seats may be attached to the pressure boundary part by fillet or partial penetration welds provided the valve seat is shouldered against the pressure boundary part.

NB-4434 Welding of Internal Structural Supports to Clad Components

Internal structural supports on clad components shall be welded to the base metal and not to the cladding, except for weld overlay cladding.

NB-4435 Welding of Nonstructural and Temporary Attachments and Their Removal

(a) Nonstructural attachments (NB-1132.1) welded to the pressure-retaining portion of the component need not comply with NB-2000 and may be welded with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (4) below are met.

- (1) The welding procedure and the welders have been qualified in accordance with NB-4321.
- (2) The material is identified and is compatible with the material to which it is attached.
- (3) The welding material is identified and compatible with the materials joined.
- (4) The welds are postweld heat treated when required by NB-4620.

(b) Removal of nonstructural attachments, when temporary, shall be accomplished as follows.

- (1) The immediate area around the temporary attachment is marked in a suitable manner so that after removal the area can be identified until after it has been examined in accordance with (3) below.
- (2) The temporary attachment is completely removed in accordance with the procedures of NB-4211.
- (3) After the temporary attachment has been removed, the marked area is examined by the liquid penetrant or magnetic particle method in accordance with the requirements of NB-5110, and meets the acceptance standards of NB-5340 or NB-5350, whichever is applicable.

(4) As an alternative to (a)(4) above, postweld heat treatment may be deferred until after removal of the attachment.

**GENERAL NOTE:**

The size of an equal leg fillet weld is the leg length of the largest inscribed right isosceles triangle.

Theoretical throat = $0.7 \times$ size of weld.

(a) Equal Leg Fillet Weld

**GENERAL NOTE:**

The size of an unequal leg fillet weld is the shorter leg length of the largest right triangle which can be inscribed within the fillet weld cross section.

(b) Unequal Leg Fillet Weld

$x \text{ min.} = 1.4t_n$ or the thickness of the hub, whichever is smaller, but not less than $1/8 \text{ in.}$, where t_n = nominal pipe wall thickness

(c) Minimum Welding Dimensions for Socket Welding Flanges

(d) Minimum Welding Dimensions for Socket Welding Fittings

FIG. NB-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS
(See NB-3661.2 for Limitation on Socket Weld Pipe Size.)

(a) Attachment of Lugs, Shoes, and Brackets

(b) Attachment of Trunnions

(c) Attachment of Rings

FIG. NB-4433-1 TYPES OF ATTACHMENT WELDS

FIG. NB-4433-1 TYPES OF ATTACHMENT WELDS

NB-4436 Installation of Attachments to Piping Systems After Testing

Attachments may be welded to the piping system after performance of the pressure test provided that:

- (a) the welds do not require PWHT under NB-4622.7;
- (b) welds shall be restricted to fillet welds not exceeding $\frac{3}{8}$ in. (10 mm) throat thickness and to full penetration welds attaching materials not exceeding $\frac{1}{2}$ in. (13 mm) in thickness;
- (c) welds shall not exceed a total length of 24 in. (610 mm) for fillet welds or 12 in. (305 mm) for full penetration welds;
- (d) welds shall be examined as required by NB-5000.

NB-4450 REPAIR OF WELD METAL DEFECTS

NB-4451 General Requirements

Defects in weld metal detected by the examinations required by NB-5000, or by the tests of NB-6000, shall be eliminated and repaired when necessary.

NB-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining, and need not be repaired by welding, provided that the requirements of (a) through (c) below are met.

- (a) The remaining thickness of the section is not reduced below that required by NB-3000.
- (b) The depression, after defect elimination, is blended uniformly into the surrounding surface.
- (c) The area is examined by a magnetic particle or liquid penetrant method in accordance with NB-5110 after blending and meets the acceptance standards of NB-5300 to ensure that the defect has been removed or reduced to an imperfection of acceptable limit. Defects detected by visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

NB-4453 Requirements for Making Repairs of Welds

Excavations in weld metal, when repaired by welding, shall meet the following requirements.

NB-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with NB-5110, and meet the acceptance standards of NB-5340 or NB-5350. This examination is not required where defect elimination removes the full thickness of the weld and where the backside of the weld joint is not accessible for removal of examination materials.

NB-4453.2 Requirements for Welding Material, Procedures, and Welders.

The weld repair shall be made using welding material, welders, and welding procedures qualified in accordance with NB-4125 and NB-4300.

NB-4453.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NB-4453.4 Examination of Repair Welds

- (a) The examination of a weld repair shall be repeated as required for the original weld, except that when the defect

was originally detected by the liquid penetrant or magnetic particle method, and when the repair cavity does not exceed the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the thickness, it need only be reexamined by the liquid penetrant or magnetic particle method.

(b) When repairs to welds joining P-No. 1 and P-No. 3 materials require examination by radiography as required in (a) above, but construction assembly prevents meaningful radiographic examination, ultrasonic examination may be substituted provided:

(1) the weld had been previously radiographed and met the applicable acceptance standards;

(2) the ultrasonic examination is performed using a procedure in accordance with Section V, Article 5, to the acceptance standards of NB-5330;

(3) the substitution is limited to Category A and B welds in vessels, and similar type welds in other items.

The absence of suitable radiographic equipment is not justification for the substitution.

NB-4453.5 Heat Treatment of Repaired Areas.

The area shall be heat treated in accordance with NB-4620.

NB-4500 BRAZING

NB-4510 RULES FOR BRAZING

NB-4511 Where Brazing May Be Used

(a) Brazing is permitted for the attachment of cladding to base material, of tubes to tubesheets, and as

Page 210

specified in NB-3671.6(a). Appurtenances and piping with outside diameter equal to that of 1 in. nominal pipe size (DN 25) and less may be fabricated using brazed joints in accordance with Fig. NB-4511-1.

(b) Valves with inlet piping connections of 4 in. nominal pipe size (DN 100) and less may have seats brazed to the valve body or bonnet provided the seat is shouldered against the pressure boundary part [Fig. NB-3544.1(c)-1].

NB-4512 Brazing Material

Where brazing is permitted, the brazing filler material and fluxes shall conform to the rules covering identification in NB-2150 and to the requirements of (a), (b), and (c) below.

(a) The filler material used in brazing shall be a nonferrous metal or alloy with a solidus temperature above 800°F (427°C) and at least 500°F (260°C) above the highest temperature of the joint in service.

(b) The filler material shall melt and flow freely by capillary action within the desired temperature range, and, in conjunction with a suitable flux or controlled atmosphere, the filler material shall wet and adhere to the surfaces to be joined.

(c) Fluxes that are fluid and chemically active at the brazing temperature shall be used, when necessary, to prevent oxidation of the filler metal and the surfaces to be joined, and to promote free flowing of the filler material.

NB-4520 BRAZING QUALIFICATION REQUIREMENTS

NB-4521 Brazing Procedure and Performance Qualification

Qualification of the brazing procedure to be used and of the performance of brazers and brazing operators is required and shall comply with the requirements of Section IX, except that validation of the procedure qualification per QB-451.5 Note (1) is not required for the furnace brazing of seat rings to bodies or bonnets of valves having inlet piping connections of 4 in. nominal pipe size (DN 100) and less. When the Design Temperature is greater than 200°F (93°C), tension testing shall be performed at the Design Temperature.

NB-4522 Brazing Requalification Requirements

In addition to the requirements of Section IX, the brazing procedure shall be set up as a new procedure specification and shall be completely requalified when the construction of the brazed components includes reheating of any portion of the completed brazed joint to a temperature that is within 300°F (167°C) of the solidus temperature of the filler metal.

NB-4530 FITTING AND ALIGNING OF PARTS TO BE BRAZED

Parts to be joined by brazing shall be fitted, aligned, and retained in position during the brazing operation within the tolerances specified in the brazing procedure specification. Brazed joints shall be assembled in a sequence which will permit the maximum number of joints to be visually examined on both sides of the joint after brazing.

NB-4540 EXAMINATION OF BRAZED JOINTS

The completed brazed joints shall be visually examined on all accessible surfaces in accordance with NB-5275.

NB-4600 HEAT TREATMENT

NB-4610 WELDING PREHEAT REQUIREMENTS

NB-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thicknesses. Some practices used for preheating are given in Appendix D as a general guide for the materials listed by P-Numbers of Section IX. It is cautioned that the preheating suggested in Appendix D does not necessarily ensure satisfactory completion of the welded joint and that the preheating requirements for individual materials within the P-Number may be more or less restrictive. The Welding Procedure Specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

NB-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does not harm the base material or any weld metal already

Page 211

Page 212

applied, or which does not introduce deleterious material into the welding area which is harmful to the weld.

- t = thickness of part penetrated
 t_n = nominal thickness of connecting part
 d = outside diameter of part B
 c = clearance or interference between mating parts and shall be in accordance with the brazing procedure specification
 z = depth of engagement and shall be the lesser of $3t_n$ or d , but in no case less than 1/4 in.

GENERAL NOTES:

- (1) Part A shall be attached to a component in accordance with the requirements for the component proper.
- (2) Part B shall be attached either to part A or to another part B by the joints shown above, or in accordance with the requirements of the component proper.
- (3) Grooves for preplaced filler metal are permitted, provided the reduction in cross section due to the grooves is considered in the design.

FIG. NB-4511-1 BRAZED CONNECTIONS FOR APPURTENANCES AND PIPING, 1 in. NOMINAL SIZE AND LESS ($\leq$ DN 25)

FIG. NB-4511-1 BRAZED CONNECTIONS FOR APPURTENANCES AND PIPING, 1 in. NOMINAL SIZE AND LESS ($\leq$ DN 25)

NB-4613 Interpass Temperature

Consideration shall be given to the limitations of interpass temperatures for quenched and tempered material to avoid detrimental effects on the mechanical properties.

NB-4620 POSTWELD HEAT TREATMENT

NB-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

NB-4622 PWHT Time and Temperature Requirements

NB-4622.1 General Requirements.³

Except as otherwise permitted in NB-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperature shall be maintained within the temperature range and for the minimum holding time specified in Table NB-4622.1-1, except as otherwise permitted in NB-4622.4(c). P-Number groups in Table NB-4622.1-1 are in accordance with QW-420 of Section IX. Except as provided in NB-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. In addition, the requirements of the following subparagraphs shall apply.

NB-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Inspector. Identification on the time-temperature recording shall be to the weld, part, or component, as applicable. A summary of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

3 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NB-4622.3 Definition of Nominal Thickness Governing PWHT.

Nominal thickness in Table NB-4622.7(b)-1 is the thickness of the weld, the pressure-retaining material for structural attachment welds or the thinner of the pressure-retaining materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. (3.2 mm). For fillet welds the nominal thickness is the throat thickness, and for partial penetration and material repair welds the nominal thickness is the depth of the weld groove or preparation.

NB-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table NB-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat treatment cycles.

(b) Holding time at temperature in excess of the minimum requirements of Table NB-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with NB-2200, NB-2400, and NB-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table NB-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table NB-4622.4(c)-1 and (1), (2), and (3) below.

(1) Except for P-No. 1 materials, when welds in the materials listed in Table NB-4622.4(c)-1 are to be postweld heat treated at the lower minimum temperatures, the impact test specimens for the welding procedure qualification required by NB-4300 shall be made using the same minimum temperatures and increased minimum holding time. Welding procedures, qualified at the temperature range and minimum holding time specified in Table NB-4622.1-1 and at the lower temperature and increased minimum holding time permitted by Table NB-4622.4(c)-1, are also qualified for any temperature in between. When such an in-between temperature is used, the minimum holding time shall be interpolated from Table NB-4622.1-1 and the alternative requirements from Table NB-4622.4(c)-1.

(2) Except for P-No. 1 materials, when welds in the materials listed in Table NB-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the welding material certification required by NB-2400 shall be made using the same minimum temperature and increased minimum holding time. Welding material certified at the temperature range and minimum holding time specified in Table NB-4622.1-1 and at the lower minimum temperatures and increased

P-Nos. 8, 34, 42, 43, 45, and hard surfacing on P-No. 1 base metal whose reported carbon content is not more than 0.30%	PWHT neither required nor prohibited				

NOTES:

(1) Exemptions to the mandatory requirements of this Table are defined in NB-4622.7.

(2) All temperatures are metal temperatures.

TABLE NB-4622.1-1 MANDATORY REQUIREMENTS FOR POSTWELD HEAT TREATMENT OF WELDS¹
minimum holding time permitted by Table NB-4622.4(c)-1 are also certified for any temperature in between.

**TABLE NB-4622.4(c)-1
ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹**

Material P-No.	Alternative Minimum Holding Temperatures, °F	Alternative Minimum Holding Times [Note (1)]
1, 3, 9A Gr. 1, 9B Gr. 1	1050	2 hr/in. thick
1, 3, 9A Gr. 1, 9B Gr. 1	1000	4 hr/in. thick

NOTE:

(1) All other requirements of NB-4622 shall apply.

TABLE NB-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

(3) Base material certified in accordance with NB-2200 may be postweld heat treated at the lower minimum temperature ranges and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation provided a higher tempering temperature is not required by the material specification.

NB-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

When materials of two different P-Number groups are joined by welding, the applicable postweld heat treatment shall be that specified in Table NB-4622.1-1 for the material requiring the higher PWHT temperature range.

NB-4622.6 PWHT Requirements for Nonpressure-Retaining Parts.

When nonpressure-retaining material is welded to pressure-retaining material, the postweld heat treatment temperature range of the pressure-retaining material shall control.

NB-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for:

- (a) nonferrous material;
- (b) welds exempted in Table NB-4622.7(b)-1;
- (c) welds subjected to temperatures above the PWHT temperature range specified in Table NB-4622.1-1, provided the

Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld filler material have been heat treated at the higher temperature;

- (d) welds connecting nozzles to components or branch to run piping provided the requirements in NB-4622.8 are met;
- (e) weld repairs to vessels provided the requirements of NB-4622.9 are met;
- (f) weld repairs to cladding after final postweld heat treatment provided the requirements of NB-4622.10 are met;
- (g) weld repairs to dissimilar metal welds after final postweld heat treatment provided the requirements of NB-4622.11 are met.

NB-4622.8 Requirements for Exempting PWHT of Nozzles to Component Welds and Branch to Run Piping Welds.

Welds connecting nozzles or branch piping of P-No. 1 materials to components or run piping of P-No. 1 or P-No. 3 materials that are not exempted from PWHT in Table NB-4622.7(b)-1 need not be given a postweld heat treatment if the requirements of (a) below are met for partial penetration and (b) below are met for full penetration welds.

- (a) The partial penetration welds are made with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal after:
 - (1) the ferritic materials to be joined are buttered or built-up with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal having a minimum thickness of $\frac{1}{4}$ in. (6 mm), and
 - (2) the heat affected zones of the buttered or built-up ferritic materials are postweld heat treated in accordance with NB-4620, without the PWHT exemptions being applied, prior to making the final welds.
- (b) The full penetration welds are made with A-No. 1 or A-No. 2 weld metal provided that:
 - (1) the component or run pipe is built-up or buttered in the area of the attachment with A-No. 1 or A-No. 2 metal having a minimum thickness of $\frac{1}{4}$ in. (6 mm);
 - (2) the A-No. 1 or A-No. 2 weld metal buildup or buttering is postweld heat treated in accordance with NB-4620 for P-No. 1 or P-No. 3 materials without the PWHT exemptions being applied;
 - (3) the welds do not penetrate through the component or run pipe thickness;
 - (4) weld metal with A-No. 1 or A-No. 2 analysis is used to join the nozzle or branch pipe of P-No. 1 material to the weld buildup or buttering;
 - (5) the nominal thickness of the weld joining the nozzle or branch pipe to the component or run pipe does not exceed $1\frac{1}{2}$ in. (38 mm) and the maximum reported carbon content of the nozzle or branch piping connection does not exceed 0.30%;
 - (6) a 200°F (93°C) minimum preheat is maintained during welding whenever the nominal thickness of the weld exceeds:

TABLE NB-4622.7(b)-1 EXEMPTIONS TO MANDATORY PWHT¹ (CONT'D)

TABLE NB-4622.7(b)-1 (CONT'D)

NOTES:

- (1) The exemptions noted in this Table do not apply to the following:
 - (a) electron beam welds in ferritic materials over $\frac{1}{8}$ in. in thickness;
 - (b) inertia and friction welds in material of any thickness of P-No. 3, P-No. 4, P-No. 5, P-No. 7 (except for Types 405 and 410S), P-No. 10, and P-No. 11 materials.
- (2) Where the thickness of material is identified in the Type of Weld column, it is the thickness of the base material at the welded joint.
- (3) Carbon level of the pressure-retaining materials being joined.
- (4) Maximum process heat input = 150,000 J/in. The maximum resulting hardness in the procedure qualification test plate shall not exceed 35 Rc.
- (5) Intermediate postweld soak at not less than 200°F for 2 hr minimum.
- (6) Intermediate postweld soak at not less than 300°F for 2 hr minimum.

TABLE NB-4622.7(b)-1 (CONT'D)

(a) $1\frac{1}{4}$ in. (32 mm) and the maximum reported carbon content of the material of the nozzle or branch pipe is 0.30% or less, or

(b) $\frac{3}{4}$ in. (19 mm) and the maximum reported carbon content of material of the nozzle or branch pipe connection exceeds 0.30%.

NB-4622.9 Temper Bead Weld Repair.

Limited weld repairs to P-No. 1 and P-No. 3 material, and A-Nos. 1, 2, 10, or 11 weld filler metal (QW-442 of Section IX), may be made without PWHT or after the final PWHT, provided it is impossible or impractical to postweld heat treat the area after repair, and provided the requirements of the following subparagraphs are met.

(a) *Examination of Area to Be Repaired.* Before repair, the area shall be examined by either the magnetic particle or liquid penetrant method in accordance with NB-5000.

(b) *Maximum Extent of Repair.* The maximum area of an individual repair based on the finished surface shall be 100 sq in. (64,500 mm²) and the depth of repair shall not be greater than one-third of the base material thickness.

(c) *Repair Welding Procedure.* The welding procedure shall be in accordance with Section IX and this Subsection and shall include the requirements of (1) through (6) below.

(1) The area to be repaired shall be suitably prepared for welding in accordance with a written procedure.

(2) The weld metal shall be deposited by the manual shielded metal arc process using low hydrogen type electrode. The maximum bead width shall be four times the electrode core diameter.

(3) The low hydrogen covered electrodes shall be baked and otherwise cared for as required by (a) through (d) below.

(a) The Certificate Holder shall bake all covered electrodes before use at a temperature of 750°F-850°F (399°C-454°C) for 30 min to 1 hr. The temperature of the oven shall not exceed 300°F (149°C) when the electrodes are placed in the oven for baking. During the baking cycle, the temperature shall not be raised more than 300°F/hr (167°C/hr) when oven temperatures are above 500°F (260°C) and the total time above 500°F (260°C), including the holding time, shall not exceed 5 hr.

(b) After baking and before the electrodes are allowed to cool below 225°F (107°C), they shall be transferred to holding ovens operating in temperature ranges of 225°F-350°F (107°C-177°C).

(c) Suitable heated portable containers shall be used at 225°F-350°F (107°C-177°C). Electrodes turned in after exposure shall be returned to the holding ovens and held at temperatures given in (b) above for a period of not less than 8 hr before reissue.

(d) Electrodes shall not be rebaked more than once, except if tests establish that the electrodes, after multiple rebakings, meet all specification requirements.

(e) If the repair area is to be subjected to a significant fast neutron fluence (greater than 10^{19} nvt $E_0 > 1$ MeV), electrode shall be limited to Cu content of 0.10% maximum (as deposited).

(4) The weld area plus a band around the repair area of at least $1\frac{1}{2}$ times the component thickness or 5 in. (127 mm), whichever is less, shall be preheated and maintained at a minimum temperature of 350°F (177°C) during welding. The maximum interpass temperature shall be 450°F (232°C). Thermocouples and recording instruments shall be used to monitor the process temperatures. Their removal shall be in accordance with NB-4435(b).

(5) The cavity shall be buttered, using a $\frac{3}{32}$ in. (2.4 mm) diameter electrode as shown in Fig. NB-4622.9(c)(5)-1. The weld bead crown surface shall be removed by grinding or machining before depositing the second layer [see Fig. NB-4622.9(c)(5)-1, Step 2]. The second layer shall be deposited with a $\frac{1}{8}$ in. (3.2 mm) diameter electrode. Subsequent layers shall be deposited with a welding electrode no larger than $\frac{5}{32}$ in. (4 mm) diameter. Bead deposition shall be

Page 218

performed in a manner shown in Fig. NB-4622.9(c)(5)-1, Step 3. The completed weld shall have at least one layer of weld reinforcement deposited and then this reinforcement shall be removed by mechanical means, making the finished surface of the repair substantially flush with the surface of the vessel surrounding the repair [Fig. NB-4622.9(c)(5)-2]. The technique described in this paragraph shall be performed in the procedure qualification test.

(6) The weld area shall be maintained at a temperature of 450°F-550°F (232°C-288°C) for a minimum period of 2 hr after completion of the weld repair in P-No. 1 materials. For P-No. 3 materials, the holding time shall be a minimum of 4 hr.

(d) *Examination of Repair Welds.* The second (temper bead) layer shall be examined by the magnetic particle or liquid penetrant method. The completed weld shall have the weld reinforcement, including the final layer, removed substantially flush with the surface prior to performing the required nondestructive examination. The nondestructive examination shall be performed after the completed weld has been at ambient temperature for a minimum period of 48 hr to detect the presence of possible delayed cracking of the weldment. The nondestructive examination of the repair welded and preheated region shall be in accordance with NB-4453.4. In addition, all repairs shall be ultrasonically examined. All nondestructive examination shall be in accordance with NB-5000.

(e) *Documentation of Weld Repairs.* Documentation of weld repairs shall be in accordance with NB-4130, exclusive of the size requirements.

(f) *Welding Procedure Qualification Test Plate.* The test assembly materials for the welding procedure qualification shall be of the same P-Number and Group Number, including a postweld heat treatment that is at least equivalent to the time and temperature applied to the materials being repaired. The depth of cavity in the test assembly shall be a minimum of one-half the depth of actual repair, but not less than 1 in. (25 mm). The test assembly thickness shall be a minimum of twice the depth of cavity in the test assembly. The test assembly shall be large enough to permit removal of the required test specimens. In order to simulate the restraint that the weld metal will experience in the repair section of the component, the test assembly dimensions surrounding the cavity shall be equal to the test assembly thickness, but not less than 6 in. (152 mm). The qualification test plate shall be prepared in accordance with Fig. NB-4622.9(f)-1.

(g) This test assembly may be used to qualify procedures for weld buildup repairs of pressure-retaining materials. In this case, the depth of the cavity shall not be less than the thickness of the weld buildup or 1 in. (25 mm), whichever is greater, and the area of the weld buildup to be applied or 54 sq in. (34,839 mm²), whichever is less.

(h) In all cases, the test assembly and cavity shall be of sufficient size to permit removal of the required test specimens.

(i) *Performance Qualifications.* If the repair weld is to be performed where physical obstructions impair the welder's ability to perform, the welder shall also demonstrate the ability to deposit sound weld metal in the positions required, using the same parameters and simulated physical obstructions as are involved in the repair.

NB-4622.10 Repair Welds to Cladding After Final Postweld Heat Treatment.

Nonpostweld heat treated weld repairs may be made to P-No. 8 or P-No. 43 cladding of P-No. 1 and P-No. 3 material after final PWHT, provided it is impossible or impractical to postweld heat treat the area after repair, and provided the requirements of the following subparagraphs are met.

(a) *Maximum Extent of Repair.* This procedure may be used with the base material exposed to a depth not greater than $\frac{1}{4}$ in. (6 mm) or 10% of the base material thickness, whichever is less, nor to an individual area greater than 100 sq in. (64,500 mm²). Areas with greater base material exposure depth shall be repaired in accordance with NB-4622.9 to within this limit before implementing the cladding repair.

(b) *Repair Welding Procedure.* The welding procedure shall be in accordance with Section IX and this Subsection, and shall include the requirements of (1) through (7) below.

(1) The repairs shall be made using A-No. 8 weld metal (Section IX, QW-442) for P-No. 8 cladding or F-No. 43 weld metal (Section IX, QW-432) for either P-No. 8 or P-No. 43 cladding.

(2) The manual shielded metal arc process shall be used for welding with a bead width not to exceed four times the electrode core diameter.

(3) All covered electrodes used for qualification test and repair welding shall be from unopened, hermetically sealed packages or heated ovens maintained between 225°F (107°C) and 350°F (177°C). Electrodes withdrawn from hermetically sealed containers or ovens for longer than 8 hr shall be discarded.

(4) During the repair, the electrodes may be maintained in heated ovens in the repair area. The oven temperature shall be maintained between 225°F (107°C) and 350°F (177°C). Electrodes exposed to the atmosphere for more than 8 hr shall be discarded.

Page 219

Page 220

Step 1: Butter cavity with one layer of weld metal using $\frac{3}{32}$ in. diameter coated electrode.

Step 2: Remove the weld bead crown of the first layer of grinding.

Step 3: The second layer shall be deposited with a $\frac{1}{8}$ in. diameter electrode. Subsequent layers shall be deposited with welding electrodes no larger than $\frac{5}{32}$ in. maximum diameter. Bead deposition shall be performed in a manner as shown. Particular care shall be taken in the application of the temper bead reinforcement weld at the tie-in points as well as its removal to ensure that the heat affected zone of the base metal and the deposited weld metal is tempered and the resulting surface is substantially flush.

FIG. NB-4622.9(c)(5)-1 TEMPER BEAD WELD REPAIR AND WELD TEMPER BEAD REINFORCEMENT

FIG. NB-4622.9(c)(5)-1 TEMPER BEAD WELD REPAIR AND WELD TEMPER BEAD REINFORCEMENT

NOTE:

- (1) Apply temper bead reinforcement weld metal to a level above the surface and then remove it substantially flush to the surface as required by NB-4622.9(c)(5).**

FIG. NB-4622.9(c)(5)-2 TEMPER BEAD REINFORCEMENT

FIG. NB-4622.9(c)(5)-2 TEMPER BEAD REINFORCEMENT

(5) The weld area plus a band around the clad repair of $1\frac{1}{2}$ times the component thickness or 5 in. (127 mm), whichever is less, shall be preheated and maintained at a minimum temperature of 350°F (177°C) during welding. The maximum interpass temperature shall be 450°F (232°C). Thermocouples and recording instruments shall be used to monitor the process temperatures. Their removal shall be in accordance with NB-4435.

(6) All areas of the base material on which weld metal is to be deposited shall be covered with a single layer of weld deposit using $\frac{3}{32}$ in. (2.4 mm) diameter electrode, followed by a minimum of one layer of weld deposit using $\frac{1}{8}$ in. (3.2 mm) diameter electrode. Subsequent layers may be deposited with electrode no larger than $\frac{5}{32}$ in. (4 mm). The weld bead crown surface of the first layer shall be removed by grinding.

(7) After completion of welding, the weld area shall be maintained at a temperature of 450°F-550°F (232°C-288°C) for a period of 2 hr for P-No. 1 material and 4 hr for P-No. 3 material.

(c) *Examination of Repair Welds.* The weld repair as well as the preheated band shall be examined by the liquid penetrant method. All nondestructive examination shall be in accordance with NB-5000.

(d) *Documentation of Weld Repairs.* Documentation of weld repairs shall be in accordance with NB-4130, exclusive of

the size requirements.

(e) Welding Procedure Qualification Test Plate

(1) The test assembly material for the welding procedure qualification test shall be of the same P-Number and Group Number, including a postweld heat treatment that is at least equivalent to the time and temperature of that applied to the material being repaired. If the repair involves two different P-Number or Group Number materials, the test assembly shall duplicate the combination.

(2) The test assembly base material shall be at least 12 in. (305 mm) by 12 in. (305 mm), 2 in. (51 mm) min. thickness, with a clad surface area of at least 8 in. (203 mm) by 8 in. (203 mm), in the area from which the bend test specimens will be removed.

(3) The qualification test plate assembly shall be prepared and tested in accordance with the requirements of Section IX. The guided bend test acceptance standards described in Section IX for cladding shall also be applicable to the HAZ of the base material.

(f) Performance Qualifications. If the repair weld is to be performed where physical obstructions impair the welder's ability to perform, the welder shall also demonstrate the ability to deposit sound weld metal in the positions required, using the same parameters and simulated physical obstructions as are involved in the repair.

NB-4622.11 Temper Bead Weld Repair to Dissimilar Metal Welds or Buttering.

Whenever PWHT is impractical or impossible, limited weld repairs to dissimilar metal welds of P-No. 1 and P-No. 3 material or weld filler metal A-No. 8 (Section IX, QW-442) or F-No. 43 (Section IX, QW-432) may be made without PWHT or after the final PWHT provided the requirements of the following subparagraphs are met.

(a) Examination of Area to Be Repaired. Before repair, the area shall be examined by either the magnetic particle or liquid penetrant method in accordance with NB-5000.

(b) Maximum Extent of Repair. Repairs made to this paragraph are limited to those along the fusion line of a nonferritic weld to ferritic base material where $\frac{1}{8}$ in. (3.2 mm) or less of nonferritic weld deposit exists above the original fusion line after defect removal. If the defect penetrates into the ferritic base material, repair of the base material may be performed in accordance with NB-4622.11 provided the depth of repair in the base material does not exceed $\frac{3}{8}$ in. (10 mm). The repairs to a completed joint shall not exceed one-half the joint thickness. The surface of the completed repair shall not exceed 100 sq in. (64,500 mm²).

(c) Repair Welding Procedure. The welding procedure and welder qualification shall meet all of the requirements of Section IX and the additional requirements of this Article. In addition, the Welding Procedure Specification shall include the following requirements.

(1) The area to be repaired shall be suitably prepared for welding in accordance with the written procedure to be used for the repair.

(2) The weld metal shall be deposited by the shielded metal arc welding process (SMAW) using A-No. 8

Page 221

Page 222

weld metal (Section IX, QW-442) for P-No. 8 to P-No. 1 or P-No. 3 weld joints or F-No. 43 weld metal (Section IX, QW-432) for either P-No. 8 or P-No. 43 to P-No. 1 or P-No. 3 weld joints. The maximum bead width shall be four times the electrode core diameter.

FIG. NB-4622.9(f)-1 QUALIFICATION TEST PLATE

FIG. NB-4622.9(f)-1 QUALIFICATION TEST PLATE

(3) All covered electrodes used for qualification test and repair welding shall be from unopened, hermetically sealed

packages or heated ovens maintained between 225°F (107°C) and 350°F (177°C). Electrodes withdrawn from hermetically sealed containers or ovens for longer than 8 hr shall be discarded.

(4) During the repair, the electrode may be maintained in heated ovens in the repair area. The oven temperature shall be maintained between 225°F (107°C) and 350°F (177°C). Electrodes exposed to the atmosphere for more than 8 hr shall be discarded.

(5) The weld area plus a band around the weld repair of $1\frac{1}{2}$ times the component thickness or 5 in. (127 mm), whichever is less, shall be preheated and maintained at a minimum temperature of 350°F (177°C) during welding. The maximum interpass temperature shall be 450°F (232°C). Thermocouples and recording instruments shall be used to monitor the metal temperature during welding. Their removal shall be in accordance with NB-4435.

(6) All areas of the ferritic base material, exposed or not, on which weld metal is to be deposited, shall be covered with a single layer of weld deposit using $\frac{3}{32}$ in. (2.4 mm) diameter electrode. The weld bead crown surface shall be removed by grinding before depositing the second layer. The second layer shall be deposited with $\frac{1}{8}$ in. (3.2 mm) diameter electrode. Subsequent layers may be deposited with $\frac{5}{32}$ in. (4 mm) maximum diameter electrode. The techniques described in this paragraph shall be duplicated in the procedure qualification. [See Fig. NB-4622.11(c)(6)-1].

(7) After at least $\frac{3}{16}$ in. (4.8 mm) of weld metal has been deposited, the preheated area as defined in (c)(5) above shall be maintained in the range of 450°F-550°F (232°C-288°C) for 4 hr as a minimum.

(8) Subsequent to the above heat treatment, the balance of the welding may be performed at a minimum preheat temperature of 100°F (38°C) and at a maximum interpass temperature of 350°F (177°C).

(d) Examination of Repair Areas

(1) After the heat treatment specified in (c)(7) above has been completed, the repaired area shall be examined by the liquid penetrant method.

(2) The repaired area and the preheated band as defined in (c)(5) above shall be examined by the liquid penetrant method after the completed weld has been at ambient temperature for a minimum of 48 hr. The repaired region shall be examined by the radiographic method and, if practical, by the ultrasonic method.

(3) For repairs to partial penetration welds, the radiographic and ultrasonic examinations specified in (d)(2) above need not be performed, if meaningful results cannot be obtained. For these cases, liquid penetrant examination only shall be performed. For weld repair depths approximately $\frac{3}{16}$ in. (4.8 mm), liquid penetrant examination shall be performed at the time specified in (d)(2) above. For weld repair depths greater than $\frac{3}{16}$ in. (4.8 mm), liquid penetrant examination shall be performed after approximately $\frac{3}{16}$ in. (4.8 mm) thickness has been deposited and the post heat specified in (c)(7) above has been completed. Additional incremental deposit thicknesses shall be liquid penetrant examined in accordance with NB-5245. The final weld surface shall be liquid penetrant examined at the time specified in (d)(2) above.

(4) All nondestructive examination shall be in accordance with NB-5000.

(e) Documentation of Weld Repairs. Documentation of weld repairs shall be in accordance with NB-4130, exclusive of the size requirements.

(f) Welding Procedure Qualification Test Plate. The test assembly materials for the welding procedure qualification shall be of the same P-Number and Group Number, including a postweld heat treatment that is at least equivalent to the time and temperature applied to the materials being repaired. The depth of cavity in the test assembly shall be a minimum of one-half the depth of actual repair but not less than 1 in. (25 mm). The test assembly thickness shall be a minimum of twice the depth of cavity in the test assembly. The test assembly shall be large enough to permit removal of the required test specimens. In order to simulate the restraint that the weld metal will experience in the repaired section of the component, the test assembly dimensions surrounding the cavity shall be equal to the test assembly thickness, but not less than 6 in. (152 mm). The qualification test plate shall be prepared in accordance with Fig. NB-4622.9(f)-1.

(g) Performance Qualifications. If the repair weld is to be performed where physical constructions impair the welder's ability to perform, the welder shall also demonstrate the ability to deposit sound weld metal in the positions required, using the same parameters and simulated physical obstructions as are involved in the repair.

using the same parameters and simulated physical obstructions as are involved in the repair.

NB-4623 PWHT Heating and Cooling Rate Requirements

Above 800°F (427°C) the rate of heating and cooling in any hourly interval shall not exceed 400°F (222°C)

Page 223

Page 224

divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°C) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 m) interval of weld length. The exceptions of (a) and (b) below are permitted.

FIG. NB-4622.11(c)(6)-1 TEMPER BEAD WELD REPAIR AND WELD TEMPER BEAD REINFORCEMENT OF DISSIMILAR METAL WELDS OR BUTTERING

FIG. NB-4622.11(c)(6)-1 TEMPER BEAD WELD REPAIR AND WELD TEMPER BEAD REINFORCEMENT OF DISSIMILAR METAL WELDS OR BUTTERING

(a) P-No. 6 material may be cooled in air from the postweld heat treatment holding temperature specified in Table NB-4622.1-1.

(b) For P-No. 7 material the cooling rate at temperatures above 1200°F shall not exceed 100°F/hr (56°C/hr), after which the rate of cooling shall be sufficiently rapid to prevent embrittlement.

NB-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

NB-4624.1 Furnace Heating - One Heat.

Heating the item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation and direct impingement of flame on the component or item is prohibited.

NB-4624.2 Furnace Heating - More Than One Heat.

The item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of NB-4624.1 apply and overlap of the heated sections of the component or item is at least 5 ft (1.5 m). When this procedure is used, the portion of the component or item outside the furnace shall be shielded so that the temperature gradient is not harmful. The cross section where the component or item projects from the furnace shall not intersect a nozzle or other structural discontinuity.

NB-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire component or item. Local postweld heat treatment shall consist of heating a circumferential band around the component or item at temperature within the ranges specified in this Subarticle. The minimum width of the controlled band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the component or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs.

NB-4624.4 Heating Items Internally.

The component or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the item. Previous to this operation, the item should be fully enclosed with insulating material.

NB-4630 HEAT TREATMENT OF WELDS OTHER THAN THE FINAL POSTWELD HEAT TREATMENT

The holding temperature, the time at temperature, the heating rate, and the cooling rate need not conform to the requirements of this Article for heat treatments other than the final postweld heat treatment.

NB-4650 HEAT TREATMENT AFTER BENDING OR FORMING FOR PIPES, PUMPS, AND VALVES

NB-4651 Conditions Requiring Heat Treatment After Bending or Forming

(a) Ferritic alloy steel pipe or formed portions of pumps or valves that have been heated for bending or other forming operations shall receive a heat treatment in accordance with NB-4620, a full anneal, a normalizing and tempering treatment, or a quenching and tempering treatment.

(b) Carbon steel pipe or formed portions of pumps or valves with a wall thickness greater than $\frac{3}{4}$ in. (19 mm) included in group P-No. 1 in Section IX that have been cold bent or formed shall receive heat treatment in accordance with NB-4620.

(c) Ferritic alloy pipe or formed portions of pumps or valves with an outside diameter greater than 4 in. (102 mm) and a wall thickness greater than $\frac{1}{2}$ in. (13 mm) included in groups P-No. 3 through P-No. 5 in Section IX that have been cold bent or formed shall require a heat treatment in accordance with NB-4620.

NB-4652 Exemptions From Heat Treatment After Bending or Forming

If the conditions described in (a) through (d) below are met, heat treatment after bending or forming is not required.

(a) Carbon steel pipe or portions of pumps and valves that have been bent or formed at a temperature

Page 225

of 1650°F (900°C) or higher shall require no subsequent heat treatment, provided the requirements of NB-4213 have been met.

(b) Austenitic stainless steel pipe, or portions of pumps or valves that have been heated for bending or other forming operations, may be used in the as-bent condition unless the Design Specifications require a heat treatment following bending or forming.

(c) Austenitic stainless steel pipe, or portions of pumps or valves that have been cold bent or formed, may be used in the as-bent condition unless the Design Specifications require a heat treatment following bending or forming.

(d) Carbon steel and ferritic alloy steel pipe, or portions of pumps or valves with sizes and wall thicknesses less than specified in NB-4651(b) and NB-4651(c), may be cold bent or formed without a heat treatment following bending.

NB-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic materials over $1\frac{1}{2}$ in. (38 mm) in thickness at the joints shall be given a grain refining heat treatment.

NB-4700 MECHANICAL JOINTS

NB-4710 BOLTING AND THREADING

NB-4711 Thread Engagement

The threads of all bolts or studs shall be engaged in accordance with the design.

NB-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the service conditions and shall not react unfavorably with either the service fluid or any component material in the system.

NB-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be seal welded.

NB-4720 BOLTING FLANGED JOINTS

In bolting gasketed flanged joints, the contact faces of the flanges shall bear uniformly on the gasket and the gasket shall be properly compressed in accordance with the design principles applicable to the type of gasket used. All flanged joints shall be made up with relatively uniform bolt stress.

NB-4730 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

Tubes or pipes of 2 in. nominal pipe size (DN 50) and less may be joined to a penetration assembly in accordance with the rules of NB-4350.

July 1, 1998
American Society Of Mechanical Engineers
SEC III D1 NB-5000
ARTICLE NB-5000 EXAMINATION

Page 227

NB-5100 GENERAL REQUIREMENTS FOR EXAMINATION

NB-5110 METHODS, NONDESTRUCTIVE EXAMINATION PROCEDURES, AND CLEANING

NB-5111 Methods

Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article.

(a) *Fabrication.* Radiographic examination shall be by film radiography or real time radioscopy in accordance with Section V, Article 2, except that fluorescent screens are not permitted for film radiography, the geometric unsharpness shall not exceed the limits of T-285, and the penetrameters of Table NB-5111-1 shall be used in lieu of those shown in Table T-276. The requirements for the retention of radioscopy images are the same as for film radiography. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; liquid penetrant examination shall be in accordance with Section V, Article 6; and leak testing shall be in accordance with Section V, Article 10.

(b) *Preservice.* Ultrasonic examinations required for weld preservice examination shall be in accordance with Section XI, Appendix 1; eddy current examination shall be in accordance with Section V, Article 8; and surface examinations shall be in accordance with NB-5111(a).

(c) The examinations required by this Article, or by reference to this Article, shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

NB-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedures shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radioscopy images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display, and Storage for Radiography and Radioscopy." Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

NB-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination materials are applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable material or procedure specifications.

NB-5120 TIME OF EXAMINATION OF WELDS AND WELD METAL CLADDING

Acceptance examinations of welds and weld metal cladding required by NB-5200 shall be performed at the times stipulated in (a) through (g) below during fabrication and installation.

(a) Radiographic examination of welds shall be performed after an intermediate¹ or final postweld heat treatment, when required, except as provided in (1) and (2) below.

1 An intermediate postweld heat treatment for this purpose is defined as a postweld heat treatment performed on a weld within a temperature range not lower than the minimum holding temperature range to which the weld shall be subjected during the final postweld heat treatment.

(1) Radiographic examination of welds in piping, pumps, and valves fabricated of P-No. 1 materials

Page 230

may be performed prior to any required postweld heat treatment.

NOTE:

(1) Hole (plaque) type penetrameters may be used on flat plates and on objects with geometries such that the penetrameter hole image is not distorted.

TABLE NB-5111-1 THICKNESS, PENETRAMETER DESIGNATIONS, ESSENTIAL HOLES, AND WIRE DIAMETERS

(2) Radiographic examination of welds in vessels fabricated of P-No. 1 materials and all welds in components fabricated of P-No. 3 materials may be performed prior to an intermediate or final postweld heat treatment, provided the welds are ultrasonically examined [NB-5111(a)] after an intermediate or final postweld heat treatment. The ultrasonic examination and acceptance standards shall be in accordance with NB-5331.

(b) Magnetic particle or liquid penetrant examinations of welds shall be performed after any required postweld heat treatment, except that welds in P-No. 1 material may be examined either before or after postweld heat treatment. The magnetic particle or liquid penetrant examination of welds at progressive stages of welding, as required in NB-5245 and NB-5246, may be performed before PWHT.

(c) All dissimilar metal weld joints, such as in austenitic or high nickel to ferritic material, or using austenitic or high nickel alloy filler metal to join ferritic materials which penetrate the wall, shall be examined after final postweld heat treatment.

(d) The magnetic particle or liquid penetrant examination of weld surfaces that are to be covered with weld metal cladding shall be performed before the weld metal cladding is deposited. The magnetic particle or liquid penetrant examination of weld surfaces that are not accessible after a postweld heat treatment shall be performed prior to the operation which caused this inaccessibility. These examinations may be performed before PWHT.

(e) Weld metal cladding shall be examined after either an intermediate¹ or final postweld heat treatment, except the examination of weld metal cladding on P-Nos. 1, 3, and 11 materials may be performed before or after the intermediate¹ or final postweld heat treatment.

(f) All of the joints in austenitic stainless steel and nonferrous material shall be examined by the liquid penetrant method after an intermediate or final postweld heat treatment, if any, is performed. This requirement does not apply to tube-to-tubesheet joints.

(g) Ultrasonic examination of electroslog welds in ferritic materials shall be performed after a grain refining heat treatment, when performed, or after final postweld heat treatment.

Page 231

NB-5130 EXAMINATION OF WELD EDGE PREPARATION SURFACES

All full penetration weld edge preparation surfaces for joint Categories A, B, C, D, and similar joints in material 2 in. (51 mm) or more in thickness shall be examined by the magnetic particle or liquid penetrant method. Indications shall be evaluated in accordance with the acceptance standards of (a), (b), and (c) below.

(a) Only indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Laminar-type imperfections are acceptable without repair if they do not exceed 1 in. (25 mm) in length. The extent of all laminar-type imperfections exceeding 1 in. (25 mm) in length shall be determined by ultrasonic examination. Imperfections exceeding 1 in. (25 mm) in length shall be repaired by welding to a depth of $\frac{3}{8}$ in. (10 mm) or the depth of the imperfection, whichever is less, unless the ultrasonic examination reveals that additional depth of repair is required to meet the ultrasonic examination requirement for the product form.

(c) Indications of nonlaminar imperfections of (1) through (3) below are unacceptable:

(1) any linear indications greater than $\frac{3}{16}$ in. (4.8 mm) long;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more indications, in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less, edge to edge.

(d) Weld repairs made to weld edge preparations for Category A, B, C, D, or similar type welds shall be examined by the magnetic particle or liquid penetrant method before the surfaces become inaccessible. The examination may be performed before or after postweld heat treatment.

NB-5140 EXAMINATION OF WELDS AND ADJACENT BASE MATERIAL

When performing the surface examinations of weld joint Categories A, B, C, and D and the equivalent welded joints in piping, pumps, and valves as required by NB-5200, the external and accessible internal weld surfaces and adjacent base material for at least $\frac{1}{2}$ in. on each side of the weld shall be included in the examination. Acceptance standards for the weld shall be as stated in this Article while the acceptance standards for base material shall be as stated in NB-2500.

NB-5200 REQUIRED EXAMINATION OF WELDS FOR FABRICATION AND PRESERVICE BASELINE

NB-5210 CATEGORY A VESSEL WELDED JOINTS AND LONGITUDINAL WELDED JOINTS IN OTHER COMPONENTS

Category A welded joints in vessels and longitudinal welded joints in other components shall be examined by a volumetric² and either the liquid penetrant or magnetic particle method.

NB-5220 CATEGORY B VESSEL WELDED JOINTS AND CIRCUMFERENTIAL WELDED JOINTS IN PIPING, PUMPS, AND VALVES

NB-5221 Vessel Welded Joints

Category B welded joints in vessels shall be examined by a volumetric² and either the liquid penetrant or magnetic particle method.

NB-5222 Piping, Pump, and Valve Circumferential Welded Joints

(a) Butt welded joints shall be examined by a volumetric² and either the liquid penetrant or magnetic particle method.

(b) Fillet and partial penetration welded joints shall be examined by either the liquid penetrant or magnetic particle method.

NB-5230 CATEGORY C VESSEL WELDED JOINTS AND SIMILAR WELDED JOINTS IN OTHER COMPONENTS

NB-5231 General Requirements

(a) Category C full penetration butt welded joints in vessels and similar welded joints in other components shall be examined by a volumetric² and either the liquid penetrant or magnetic particle method.

(b) Category C full penetration corner welded joints and similar welded joints in other components shall be ultrasonically or radiographically examined and either liquid penetrant or magnetic particle examined.

2 A radiographic examination [NB-5111(a)] is required; a preservice examination [NB-5111(b)] may or may not be required for compliance to the Design Specification [NCA-3252(c)].

Page 232

(c) Type 2 Category C full penetration corner welded joints similar to Fig. NB-4243-1 sketches (d), (e), and (f) also require the fusion zone and the parent metal beneath the attachment surface to be ultrasonically examined after welding to verify freedom from lack of fusion and laminar defects.

(d) Category C partial penetration and fillet welded joints, and similar welded joints in other components shall be examined by either the magnetic particle or liquid penetrant method on all accessible surfaces.

NB-5240 CATEGORY D VESSEL WELDED JOINTS AND BRANCH AND PIPING CONNECTIONS IN OTHER COMPONENTS

NB-5241 General Requirements

All Category D welded joints in vessels and similar welded joints in other components shall be examined as stated in the following paragraphs.

NB-5242 Full Penetration Butt Welded Nozzles, Branch, and Piping Connections

Nozzles, branch, and piping connections attached by full penetration butt welded joints as shown in Fig. NB-4244(a)-1 shall be examined by the radiographic and either the liquid penetrant or magnetic particle method.

NB-5243 Corner Welded Nozzles, Branch, and Piping Connections

(a) Full penetration corner welded nozzles in vessels as shown in Fig. NB-4244(b)-1 shall be examined by either the ultrasonic or the radiographic method, and either the liquid penetrant or magnetic particle method. If radiographed, the weld fusion zone and the parent metal beneath the attachment surface for details shown in Fig. NB-4244(b)-1 sketches (a), (b), (c), (d), (e), and (g) shall be ultrasonically examined after welding to assure freedom from lack of fusion and laminar defects.

(b) Full penetration corner welded branch and piping connections exceeding 4 in. nominal pipe size (DN 100) in piping, pumps, and valves, as shown in Fig. NB-4244(b)-1, shall be examined by either the ultrasonic or the radiographic method, and either the liquid penetrant or magnetic particle method.

(c) Full penetration corner welded branch and piping connections with 4 in. and less nominal pipe size ($\leq$ DN 100) in piping, pumps, and valves shall be examined by either the magnetic particle or liquid penetrant method.

NB-5244 Weld Metal Buildup at Openings for Nozzles, Branch, and Piping Connections

(a) When weld metal buildup is made to a surface as shown in Step 1 of Fig. NB-4244(c)-1, the weld metal buildup, the fusion zone, and the parent metal beneath the weld metal buildup shall be ultrasonically examined to ensure freedom from lack of fusion and laminar defects. Nozzles, branch, and piping connections may then be attached by a full penetration weld as shown in Step 2 of Fig. NB-4244(c)-1. The full penetration butt welded joint shall be examined by either the ultrasonic or radiographic method, and either the liquid penetrant or magnetic particle method.

(b) For branch and piping connections with 4 in. and less nominal pipe size ($\leq$ DN 100) in piping, pumps, and valves, full penetration welds shown in sketch (c) of Fig. NB-4244(c)-1 shall be examined in accordance with NB-5243(c).

NB-5245 Partial Penetration Welded Joints

Partial penetration welded joints, as permitted in NB-3352.4(d), and as shown in Figs. NB-4244(d)-1 and NB-4244(d)-2, shall be examined progressively using either the magnetic particle or liquid penetrant methods. The increments of examination shall be the lesser of one-half of the maximum welded joint dimension measured parallel to the center line of the connection or $\frac{1}{2}$ in. (13 mm). The surface of the finished welded joint shall also be examined by either method.

NB-5246 Oblique Full Penetration Nozzles, Branch, and Piping Connections

(a) Full penetration oblique nozzles in vessels as shown in Fig. NB-4244(e)-1 shall be examined by either the ultrasonic or radiographic method, and either the liquid penetrant or magnetic particle method. In addition, the weld, the fusion zone, and the parent metal beneath the attachment surface for details shown in Fig. NB-4244(e)-1, sketches (a), (b), and (c) shall be ultrasonically examined after welding to assure freedom from lack of fusion and laminar defects.

(b) Full penetration oblique welded joint branch and piping connections in piping, pumps, and valves, as shown in Fig. NB-4244(e)-1, shall be examined in accordance with the requirements for corner welded

Page 233

branch and piping connections specified in NB-5243(b) and (c), as applicable.

NB-5260 FILLET, PARTIAL PENETRATION, SOCKET, AND ATTACHMENT WELDED JOINTS

NB-5261 Fillet, Partial Penetration, and Socket Welded Joints

Fillet and partial penetration welded joints, except for nonstructural attachments (NB-1132.1), and socket welds shall be examined by the magnetic particle or liquid penetrant method.

NB-5262 Structural Attachment Welded Joints

Structural attachment welded joints made to pressure-retaining material shall be examined by either the magnetic particle or liquid penetrant method.

NB-5270 SPECIAL WELDED JOINTS

NB-5271 Welded Joints of Specially Designed Seals

Welded joints of this type shall be examined by either the magnetic particle or liquid penetrant method.

NB-5272 Weld Metal Cladding

Weld metal cladding shall be examined by the liquid penetrant method.

NB-5273 Hard Surfacing

Hard surfacing weld metal shall be examined by the liquid penetrant method in accordance with NB-2546, and the acceptance standards applicable to materials less than $\frac{5}{8}$ in. (16 mm) thick shall apply. Penetrant examination is not

required for hard surfacing on valves with inlet connections 4 in. nominal pipe size (DN 100) or less.

NB-5274 Tube-to-Tubesheet Welded Joints

Tube-to-tubesheet welded joints shall be examined by the liquid penetrant method.

NB-5275 Brazed Joints

Flux and flux residue shall be removed from all surfaces prior to examination. Joints shall be visually examined on all accessible surfaces to determine whether there has been adequate flow of brazing metal through the joint. Optical aids may be employed for indirect visual examination of joints which cannot be directly examined.

NB-5276 Inertia and Continuous Drive Friction Welds

(a) When radiographic examination is required by this Article, inertia and continuous drive friction welds shall also be examined by the ultrasonic method to verify bonding over the entire area.

(b) The materials used shall be those assigned a P-Number by Section IX, but shall not include rimmed or semikilled steel.

(c) One of the two parts to be joined must be held in a fixed position and the other part rotated. The two faces to be joined must be symmetrical with respect to the axis of rotation.

(d) The weld between the two members shall be a full penetration weld.

NB-5277 Electron Beam Welds

In addition to the requirements for the type of weld being examined, all complete penetration welds made by the electron beam welding process shall be ultrasonically examined.

NB-5278 Electroslag Welds

In addition to the requirements for the type of weld being examined, all complete penetration welds made by the electroslag welding process in ferritic materials shall be ultrasonically examined.

NB-5279 Special Exceptions

When the joint detail does not permit radiographic examination to be performed in accordance with procedures of this Subsection for joints attaching penetration assemblies, which are fabricated as appurtenances or of the closing seam within an electrical penetration assembly, not necessarily fabricated as an appurtenance, ultrasonic examination plus liquid penetrant or magnetic particle examination of the completed weld may be substituted for the radiographic examination. The absence of suitable radiographic equipment shall not be justification for such substitution. The substitution of ultrasonic examination can be made provided the examination is performed using a detailed written procedure which has been proven by actual demonstration to the

Page 234

satisfaction of the Inspector as capable of detecting and locating defects described in this Subsection. The nondestructive examination shall be in accordance with Section V and meet the acceptance standards of NB-5300.

NB-5280 PRESERVICE EXAMINATION

NB-5281 General Requirements

(a) Examinations required by NCA-3252(c) shall be completed prior to completion of the N-5 Data Report.

(b) All volumetric and surface examinations shall be documented with results and identified in a form consistent with those required in NCA-4134.17 for transfer to the Owner.

NB-5282 Examination Requirements

(a) Components shall be examined as specified in Section XI, Table IWB-2500-1. The method of examination for the components and parts of the pressure-retaining boundaries shall comply with those tabulated in Table IWB-2500-1. Only the volumetric and surface examinations are required to be performed.

(b) For Control Rod housings, Examination Category B-O, the examination shall be extended to include essentially 100% of the welds in the installed peripheral control rod drive housing only.

NB-5283 Components Exempt From Preservice Examination

The following components or parts of components are exempted from the volumetric and surface examination requirements of this subarticle:

(a) piping of NPS 1 (DN 25) and smaller, except for steam generator tubing;

(b) reactor vessel head connections and associated piping, NPS 2 (DN 50) and smaller, made inaccessible by control rod drive penetrations; and

(c) integral attachments of supports and restraints that are inaccessible due to being encased in concrete, buried underground, or encapsulated by guard pipe.

NB-5300 ACCEPTANCE STANDARDS

NB-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following conditions:

(a) any indication characterized as a crack or zone of incomplete fusion or penetration;

(b) any other elongated indication which has a length greater than:

(1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive

(2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive

(3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm) where t is the thickness of the thinner portion of the weld;

(c) internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable, as provided in (b) above;

(d) any group of aligned indications having an aggregate length greater than t in a length of $12t$, unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(e) rounded indications in excess of that shown as acceptable in Appendix VI.

NB-5330 ULTRASONIC ACCEPTANCE STANDARDS

NB-5331 Fabrication

All imperfections which produce a response greater than 20% of the reference level shall be investigated to the extent that the operator can determine the shape, identity, and location of all such imperfections and evaluate them in terms of the acceptance standards given in (a) and (b) below.

(a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:

(1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive

(2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive

(3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

NB-5332 Preservice Examination

(a) Components whose volumetric examination reveals flaws that meet the acceptance standards of Section XI, IWB-3000 shall be acceptable. The flaws will be dimensioned and recorded in accordance with Section V, Article 4 and this Subsection.

(b) Components whose volumetric examination reveals flaws that exceed the standards of IWB-3000 are not acceptable for service and shall be repaired.

NB-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

NB-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication that is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications that would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NB-5342 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks and linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

NB-5343 Preservice Examination

Components whose surface examination reveals flaws that meet the acceptance standards of NB-2500 and NB-5300 shall be acceptable and recorded as required by NB-5281(b).

NB-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

NB-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities, such as may occur from machining marks, surface conditions, or an incomplete bond between base metal and cladding, may produce similar indications which are nonrelevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NB-5352 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks or linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

Page 236

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

NB-5353 Preservice Examination

Components whose surface examination reveals flaws that meet the acceptance standards of NB-2500 and NB-5300 shall be acceptable and recorded as required by NB-5281(b).

NB-5360 EDDY CURRENT PRESERVICE EXAMINATION OF INSTALLED NONFERROMAGNETIC STEAM GENERATOR HEAT EXCHANGER TUBING

Flaws revealed during preservice examination of installed nonferromagnetic heat exchanger tubing shall be evaluated using the criteria in the Design Specification [NCA-3252(c)].

NB-5370 VISUAL ACCEPTANCE STANDARDS FOR BRAZED JOINTS

Braze metal shall give evidence of having flowed uniformly through a joint by the appearance of an uninterrupted, narrow visible line of brazing alloy at the end of the joint.

NB-5380 BUBBLE FORMATION TESTING

Bubble formation testing shall be in accordance with Section V, Article 10. When vacuum box testing is used, the soak time shall be a minimum of 10 sec. Any indication of leaking, by the formation of bubbles or by the breaking of the continuous soap film by leaks, shall be evidence of an unacceptable condition.

NB-5400 FINAL EXAMINATION OF VESSELS

NB-5410 EXAMINATION AFTER HYDROSTATIC TEST

After the pressure test of a vessel:

(a) All weld joints and heat affected zones of Categories A, B, C, and D, used to join ferritic material and repair welds in ferritic material that exceed in depth either $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, whichever is less, shall be examined when physically accessible by the magnetic particle or liquid penetrant method.

(b) All required volumetric preservice examinations shall be performed.

NB-5500

NB-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

NB-5510 GENERAL REQUIREMENTS

Organizations performing Code required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by NB-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of NB-5520. All nondestructive examinations required by this Subsection shall be performed by and the results evaluated by qualified nondestructive examination personnel.

NB-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

3 SNT-TC-1A is a Recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, OH 43228-0518. SNT-TC-1A-1992 is the applicable edition.

4 Personnel qualified by examination and certified to the previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

5 Employer as used in this Article shall include: N Certificate Holders; Quality System Certificate Holders; Material Organizations who are qualified in accordance with NCA-3862(a)(1); and organizations who provide subcontracted nondestructive examination services to organizations described above.

NB-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended guidelines of SNT-TC-1A.³⁴ The Employer's⁵ written practice, required by paragraph 5 of SNT-TC-1A, shall identify the requirements relative to the recommended guidelines. The recommended guidelines

Page 237

of SNT-TC-1A shall be considered as minimum requirements, except as modified in (1) through (5) below.

(1) Qualification of Level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by Employer,⁵ ASNT, or an outside agency.

(b) The specific examination, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by the Employer or an outside agency. The Employer or outside agency administering the specific examination shall identify the minimum grade requirement in the written program when the basic and method examinations have been administered by ASNT, which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The time of training and experience shall be described in the written practice, and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

The minimum classroom training times identified in Table 6.3.1 of SNT-TC-1A may be reduced from 8 and 16 hours to 4 and 8 hours, respectively, for visual examination personnel.

(4) For visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests, and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or Level III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in

the written instructions.

(6) Personnel performing the volumetric preservice examination using the ultrasonic method shall meet the requirements of Section XI, Appendix VII, and Appendix VIII when required by Appendix I.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subjection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

NB-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of Levels I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [NB-5521(a)(1)(a)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

NB-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Organizations and qualified by them in accordance with NCA-3820 and subcontractors who provide nondestructive examination services to them.

NB-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NB-6000

ARTICLE NB-6000 TESTING

Page 239

NB-6100 GENERAL REQUIREMENTS

NB-6110 PRESSURE TESTING OF COMPONENTS, APPURTENANCES, AND SYSTEMS

NB-6111 Scope of Pressure Testing

All pressure-retaining components, appurtenances, and completed systems shall be pressure tested. The preferred method shall be a hydrostatic test using water as the test medium. Bolts, studs, nuts, washers, and gaskets are exempted from the pressure test.

NB-6112 Pneumatic Testing

A pneumatic test in accordance with NB-6300 may be substituted for the hydrostatic test when permitted by NB-6112.1 (a).

NB-6112.1 Pneumatic Test Limitations

(a) A pneumatic test may be used in lieu of a hydrostatic test only when any of the following conditions exists:

(1) when components, appurtenances, or systems are so designed or supported that they cannot safely be filled with liquid;¹

(2) when components, appurtenances, or systems which are not readily dried are to be used in services where traces of the testing medium cannot be tolerated.

(b) A pneumatic test at a pressure not to exceed 25% of the Design Pressure may be applied, prior to either a hydrostatic or a pneumatic test, as a means of locating leaks.

1 These tests may be made with the item being tested partially filled with liquid, if desired.

NB-6112.2 Precautions to Be Employed in Pneumatic Testing.

Compressed gaseous fluid is hazardous when used as a testing medium. Therefore, it is recommended that special precautions for protection of personnel be taken when a gaseous fluid under pressure is used as a test medium.

NB-6113 Witnessing of Pressure Tests

Pressure testing required by this Article shall be performed in the presence of the Inspector, except that testing of each line valve and each pump having piping connections of 4 in. nominal pipe size (DN 100) and less need not be witnessed by the Inspector. For line valves and pumps 4 in. nominal pipe size (DN 100) and less, the Inspector's review and acceptance of the Certificate Holder's test records will be authorization to sign the Data Report Form and take precedence over NCA-5280.

NB-6114 Time of Pressure Testing

NB-6114.1 System Pressure Test.

The installed system shall be pressure tested prior to initial operation.

(a) The pressure test may be performed progressively on erected portions of the system.

(b) Systems which are open ended, such as spray systems, may be pressure tested with the nozzle attachment opening plugged. The spray nozzles and their attachment weld joints or mechanical joints need not be pressure tested.

NB-6114.2 Component and Appurtenance Pressure Test

(a) Components and appurtenances shall be pressure tested prior to installation in a system, except as permitted in (b) below.

(b) The system pressure test may be substituted for a component or appurtenance pressure test, provided:

(1) the component can be repaired by welding in accordance with the rules of NB-4130 and NB-4450, if required, as a result of the system pressure test;

(2) the component repair weld can be postweld heat treated in accordance with NB-4620, if required,

Page 242

and nondestructively examined in accordance with the rules of NB-4130 and NB-4450, as applicable;

(3) the component is resubjected to the required system pressure test following the completion of repair and examination if the repair is required to be radiographed by NB-4453.4.

(c) Valves require pressure testing prior to installation in a system in accordance with NB-3500.

(d) Items which, when assembled, form a completed pump or valve may be tested in the form of subassemblies, provided:

- (1) the test pressure is in accordance with the requirements of NB-6221;
- (2) the pressure test is performed in a manner which, in the subassembly under test, will simulate the loadings present when the completed pump or valve is assembled and pressurized;
- (3) the component Certificate Holder approves any pressure test of component subassemblies;
- (4) the component Certificate Holder specifies the pressure test requirements and test pressure to be used;
- (5) each subassembly pressure test is performed by a Certificate Holder and is performed in the presence of the Authorized Inspector;
- (6) each subassembly pressure tested by other than the component Certificate Holder is stamped with the NPT symbol, except as provided in NCA-8330. The test pressure shall be identified on the Partial Data Report Form.
- (7) each subassembly pressure tested by other than the component Certificate Holder is listed on the Code Data Report Form;
- (8) the pressure tested subassemblies of pumps or valves are subsequently assembled by mechanical methods only;
- (9) welds examined during the subassembly pressure test need not be reexamined during the system pressure test.

NB-6114.3 Material Pressure Test.

The component or appurtenance pressure test may be used in lieu of any such test required by the material specification for a part or material used in the component or appurtenance, provided:

- (a) nondestructive examinations, if required by the material specification, can be performed subsequent to the component or appurtenance pressure test;
- (b) the material can be repaired by welding in accordance with the rules of NB-4130, if required, as a result of the pressure test;
- (c) postweld heat treatment, when required after repairs, can be performed in accordance with NB-4620.

NB-6115 Machining After Pressure Test

An additional amount of material, not to exceed 10% of the wall thickness or $\frac{3}{8}$ in. (10 mm), whichever is less, is permitted on the completed component during pressure testing where machining to critical dimensions and tolerances is required.

NB-6120 PREPARATION FOR TESTING

NB-6121 Exposure of Joints

All joints, including welded joints, shall be left uninsulated and exposed for examination during the test.

NB-6122 Addition of Temporary Supports

Components designed to contain vapor or gas may be provided with additional temporary supports, if necessary, to support the weight of the test liquid.

NB-6123 Restraint or Isolation of Expansion Joints

Expansion joints shall be provided with temporary restraints, if required, for the additional pressure load under test.

NB-6124 Isolation of Equipment Not Subjected to Pressure Test

Equipment that is not to be subjected to the pressure test shall be either disconnected from the component or system or

isolated during the test by a blind flange or similar means. Valves may be used if the valves with their closures are suitable for the proposed test pressure.

NB-6125 Treatment of Flanged Joints Containing Blanks

Flanged joints at which blanks are inserted to isolate other equipment during the test need not be retested.

NB-6126 Precautions Against Test Medium Expansion

If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure.

Page 243

NB-6127 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all low pressure filling lines and other items that should not be subjected to the test have been disconnected or isolated.

NB-6200 HYDROSTATIC TESTS

NB-6210 HYDROSTATIC TEST PROCEDURE

NB-6211 Venting During Fill Operation

The component or system in which the test is to be conducted shall be vented during the filling operation to minimize air pocketing.

NB-6212 Test Medium and Test Temperature

(a) Water or an alternative liquid, as permitted by the Design Specification, shall be used for the hydrostatic test.

(b) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture (Appendix G). The test pressure shall not be applied until the component, appurtenance, or system and the pressurizing fluid are at approximately the same temperature.

NB-6220 HYDROSTATIC TEST PRESSURE REQUIREMENTS

NB-6221 Minimum Hydrostatic Test Pressure

(a) The installed system shall be hydrostatically tested at not less than 1.25 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of NB-7000.

(b) Valves shall be hydrostatically tested in accordance with the rules of NB-3500.

(c) Components shall be hydrostatically tested at not less than 1.25 times their Design Pressure.

NB-6222 Maximum Permissible Test Pressure

The stress limits specified in NB-3226 shall be used in determining the maximum permissible test pressure. In multichamber components, pressure may be simultaneously applied to the appropriate adjacent chamber to satisfy these stress limits.

NB-6223 Hydrostatic Test Pressure Holding Time

The hydrostatic test pressure shall be maintained a minimum of 10 min prior to initiation of the examination for leakage required by NB-6224.

NB-6224 Examination for Leakage After Application of Pressure

Following the application of the hydrostatic test pressure for the required time (NB-6223), all joints, connections, and regions of high stress, such as regions around openings and thickness transition sections, shall be examined for leakage. Except in the case of pumps and valves which shall be examined while at test pressure, this examination shall be made at a pressure equal to the greater of the Design Pressure or three-fourths of the test pressure and it shall be witnessed by the Inspector. Leakage of temporary gaskets and seals, installed for the purpose of conducting the hydrostatic test and which will be replaced later, may be permitted unless the leakage exceeds the capacity to maintain system test pressure for the required amount of time. Other leaks, such as those from permanent seals, seats, and gasketed joints in components, may be permitted when specifically allowed by the Design Specification. Leakage from temporary seals or leakage permitted by the Design Specification shall be directed away from the surface of the component to avoid masking leaks from other joints.

NB-6300 PNEUMATIC TESTS

NB-6310 PNEUMATIC TESTING PROCEDURES

NB-6311 General Requirements

When a pneumatic test is performed, it shall be conducted in accordance with the requirements of NB-6100 and this Subarticle.

NB-6312 Test Medium and Test Temperature

(a) The gas used as the test medium shall be nonflammable.

(b) Testing temperature shall be in accordance with NB-6212(b).

Page 244

NB-6313 Procedure for Applying Pressure

The pressure in the system shall gradually be increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached.

NB-6320 PNEUMATIC TEST PRESSURE REQUIREMENTS

NB-6321 Minimum Required Pneumatic Test Pressure

(a) The installed system shall be pneumatically tested at not less than 1.2 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of NB-7000.

(b) Valves shall be pneumatically tested in accordance with the rules of NB-3500.

(c) Components shall be pneumatically tested at not less than 1.2 times their Design Pressure.

NB-6322 Maximum Permissible Test Pressure

The maximum test pressure shall be limited as defined in NB-6222.

NB-6323 Test Pressure Holding Time

The test pressure of NB-6321 shall be maintained for a minimum total time of 10 min.

NB-6324 Examination for Leakage After Application of Pressure

Following the application of pressure for the time specified in NB-6323, the test pressure shall be reduced to a value

equal to the greater of the Design Pressure or three-fourths of the test pressure and held for a sufficient time to permit examination as defined in accordance with NB-6224.

NB-6400 PRESSURE TEST GAGES

NB-6411 Types of Gages to Be Used and Their Location

Pressure test gages used in pressure testing shall be indicating pressure gages and shall be connected directly to the component. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator for the duration of the test. For systems with a large volumetric content, it is recommended that a recording gage be used in addition to the indicating gages.

NB-6412 Range of Indicating Pressure Gages

(a) Analog type indicating pressure gages used in testing shall be graduated over a range not less than $1\frac{1}{2}$ times nor more than 4 times the test pressure.

(b) Digital type pressure gages may be used without range restriction provided the combined error due to calibration and readability does not exceed 1% of the test pressure.

NB-6413 Calibration of Pressure Test Gages

All test gages shall be calibrated against a standard dead weight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests using the same pressure test gage or gages which is conducted at the same site within a period not exceeding 2 weeks.

NB-6600 SPECIAL TEST PRESSURE SITUATIONS

NB-6610 COMPONENTS DESIGNED FOR EXTERNAL PRESSURE

Components designed for external pressure only shall be subjected to an internal test pressure at 1.25 times the design external pressure. The pressure shall be under proper control so that the required test pressure is never exceeded by more than 6%.

NB-6620 PRESSURE TESTING OF COMBINATION UNITS

NB-6621 Pressure Chambers Designed to Operate Independently

Pressure chambers of combination units that have been designed to operate independently shall be hydrostatically tested as separate vessels; that is, each chamber shall be tested without pressure in the adjacent chamber.

Page 245

NB-6622 Common Elements Designed for a Maximum Differential Pressure

(a) When pressure chambers of combination units have their common elements designed for the maximum differential pressure that can occur during startup, operation, and shutdown, and the differential pressure is less than the higher of the Design Pressures of the adjacent chambers, the common elements shall be subjected to a hydrostatic test pressure of at least $1\frac{1}{4}$ times the maximum differential pressure.

(b) Following the test of the common elements, as required by (a) above and their inspection, the adjacent chambers shall be hydrostatically tested (NB-6221). Care must be taken to limit the differential pressure between the chambers to the pressure used when testing the common elements.

July 1, 1998

American Society Of Mechanical Engineers

NB-7100 GENERAL REQUIREMENTS

NB-7110 SCOPE

(a) A system¹ shall be protected from the consequences arising from the application of conditions of pressure and coincident temperature that would cause either the Design Pressure or the Service Limits specified in the Design Specification to be exceeded.

(b) Pressure relief devices² are required when the operating conditions considered in the Overpressure Protection Report would cause the Service Limits specified in the Design Specification to be exceeded.

(c) Protection of the system from the effects of pressure increases of extremely short duration, such as water hammer resulting from the rapid closing of a valve, is beyond the scope of this Article. These effects shall be included in the Design Specification.

(d) Rules covering the design of reactor shutdown systems and their application as an integrated part of system overpressure protection are beyond the scope of this Article. Appropriate guidance is found in engineering standards and in requirements of the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

1 Wherever the word system appears in this Article, it refers to the component or group of components for which overpressure protection is provided as described in the Overpressure Protection Report.

2 A pressure relief device is designed to open to prevent a rise of internal fluid pressure, greater than a specified value, resulting from exposure to pressure transient conditions. It may be a pressure relief valve or a nonreclosing pressure relief device.

NB-7111 Definitions

(a) *Overpressure* is that pressure which exceeds the Design Pressure and is caused by increases in system fluid pressure resulting from thermal imbalances, excess pump flow, and other similar phenomena capable of causing a system pressure increase of a sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices listed in this Article.

(b) The basic definitions of pressure relief devices as specified in this Article are given in ASME PTC 25-1994, Pressure Relief Devices.

(c) *Primary pressure* is the pressure of the fluid at the inlet of the pressure relief device.

(d) *Secondary pressure* is that value of pressure existing in the passage between the actual discharge area and the outlet for which the discharge system of the pressure relief devices shall be designed.

NB-7120 INTEGRATED OVERPRESSURE PROTECTION

Overpressure protection of the components shall be provided by any of the following as an integrated overpressure protection:

(a) the use of pressure relief devices and associated pressure sensing elements;

(b) the use of the reactor shutdown system;

(c) a design without pressure relief devices that does not exceed the Service Limits specified in the Design Specifications [NB-7110(b)].

NB-7130 VERIFICATION OF THE OPERATION OF RECLOSING PRESSURE RELIEF DEVICES

NB-7131

(a) Reclosing pressure relief devices shall be constructed so that potential impairment of the overpressure protection function from service exposure to fluids can be determined by test or examination.

(b) Means shall be provided for remote monitoring of valve position (fully open and fully closed). These means may be incorporated in the valve design or its system installation.

Page 252

(c) Reclosing pressure relief devices and their associated pressure sensing elements shall be so constructed that their correct operation can be demonstrated under service or test conditions, as may be required by regulatory or enforcement authorities having jurisdiction at the nuclear power plant site.

NB-7140 INSTALLATION

NB-7141 Pressure Relief Devices

(a) Pressure relief devices shall be as close as practicable to the major source of overpressure anticipated to arise within the system under the conditions summarized in the Overpressure Protection Report (NB-7200).

(b) The connection between a system and its pressure relief device shall have a minimum inside diameter equal to or greater than the nominal inside diameter of the pressure relief device inlet. The opening in the connection shall be designed to provide direct and unobstructed flow between the system and the pressure relief device.

(c) The connection between a system and its safety valve shall be not longer than the face-to-face dimension of the corresponding tee fitting of the same dimension and pressure rating listed in ANSI B16.5, ANSI B16.9, or ANSI B16.11. Alternatively the connection shall not result in accumulative line losses greater than 2% of the relieving pressure.

(d) The connection between a system and its safety relief valve or relief valve shall not result in accumulated line losses greater than 3% of the relieving pressure.

(e) Safety, safety relief, and relief valves shall be installed in an upright position.

(f) The flow area of the discharge piping connected to a pressure relief device shall not be less than the flow area of the device outlet. Back pressure that may exist or develop shall not reduce the relieving capacity of the relieving device(s) below that required to protect the system; potential for flashing shall be considered.

(g) Valve installation not in accordance with (c), (d), (e), and (f) above may be used provided:

(1) the NV Certificate Holder confirms that the valve design is satisfactory for the intended installation and satisfies the requirements of the valve Design Specification;

(2) the valves are adjusted for acceptable performance in conformance with the requirements of the valve Design Specification;

(3) technical justification for the adequacy of the installation is provided in the Overpressure Protection Report, including verification that the requirements of (1) and (2) have been met.

(h) A pressure relief valve certified for steam service may be installed on an inlet water loop seal³ if the following conditions are met:

(1) the loop seal water purge time is considered and included in the Overpressure Protection Report;

(2) the requirements of NB-7510, NB-7520, and NB-7732.2 as applicable are met and the pressure relief valve set pressure is established on steam.

NB-7142 Stop Valves

(a) No stop valve or other device shall be placed in such a location relative to a pressure relief device, that it could reduce the overpressure protection below that required by the rules of this Article, unless such stop valves are constructed and installed with controls and interlocks so that the relieving capacity requirements of NB-7300 are met under all conditions of operation of both the system and the stop valves.

of operation of both the system and the stop valves.

(b) Simple administrative control of stop valve position is not acceptable.

(c) Stop valves shall have independent and diverse interlocks to prevent valves from being closed during all conditions of system operation when the pressure relief device is needed to meet the requirements of NB-7300.

(d) Stop valves shall have independent and diverse interlocks to assure that the valves will automatically open and remain open during all conditions of system operation when the pressure relief device is needed to meet the requirements of NB-7300.

(e) Means shall be provided to permit verification of the operation of controls and interlocks.

NB-7143 Draining of Pressure Relief Devices

(a) A pressure relief device installation shall be fitted with a drain at its lowest point where liquid or residue can collect, if such liquid or residue could interfere with proper relieving operation.

(b) If the design of a pressure relief device permits liquid or residue to collect on the discharge side of the disk and could interfere with the proper relieving operation, the device shall be fitted with a drain to minimize the collection of liquid or residue.

(c) Drains shall discharge to a controlled thermal dissipation or discharge storage system.

3 An inlet water loop seal consists of valve inlet piping that is configured to from a water seal below the pressure relief valve seat which separates the normal system relieving fluid (steam) from the valve seat.

Page 253

NB-7150 ACCEPTABLE PRESSURE RELIEF DEVICES

NB-7151 Pressure Relief Valves⁴

Pressure relief valves may be used in accordance with NB-7170 and NB-7500.

NB-7152 Nonreclosing Pressure Relief Devices⁵

Nonreclosing pressure relief devices may be used in accordance with NB-7170 and NB-7600.

NB-7160 UNACCEPTABLE PRESSURE RELIEF DEVICES

NB-7161 Deadweight Pressure Relief Valves

Dead weight valves shall not be used.

NB-7170 PERMITTED USE OF PRESSURE RELIEF DEVICES

NB-7171 Safety Valves⁶

Safety valves, meeting the requirements of NB-7510, may be:

(a) steam service;

(b) air and gas service.

NB-7172 Safety Relief Valves⁷

Safety relief valves, meeting the requirements of NB-7510, may be used for:

(a) steam service;

(b) air and gas service;

(c) liquid service.

NB-7173 Relief Valves⁸

Relief valves, meeting the requirements of NB-7510, may be used for liquid service.

4 A pressure relief valve is a pressure relief device which is designed to reclose and prevent the further flow of fluid after normal conditions have been restored.

5 A nonreclosing pressure relief device is a pressure relief device designed to remain open after operation.

6 A safety valve is a pressure relief valve actuated by inlet static pressure and characterized by rapid opening or pop action.

7 A safety relief valve is a pressure relief valve characterized by rapid opening pop action, or by opening generally proportional to the increase in pressure over the opening pressure.

8 A relief valve is a pressure relief valve actuated by inlet static pressure and having a gradual lift generally proportional to the increase in pressure over the opening pressure.

NB-7174 Pilot Operated Pressure Relief Valves⁹

Pilot operated pressure relief valves, meeting the requirements of NB-7520, may be used for:

- (a) steam service;
- (b) air and gas service;
- (c) liquid service.

NB-7175 Power Actuated Pressure Relief Valves¹⁰

Power actuated pressure relief valves, meeting the requirements of NB-7530, may be used for:

- (a) steam service;
- (b) air and gas service;
- (c) liquid service.

NB-7176 Safety Valves With Auxiliary Actuating Devices

Safety valves with auxiliary actuating devices, meeting the requirements of NB-7540, may be used for steam service.

NB-7177 Pilot Operated Pressure Relief Valves With Auxiliary Actuating Devices

Pilot operated pressure relief valves with auxiliary actuating devices, meeting the requirements of NB-7540, may be used for:

- (a) steam service;
- (b) air and gas service;
- (c) liquid service.

NB-7178 Nonreclosing Devices

Rupture disk devices¹¹ may be used on air or gas service in accordance with NB-7600.

9 A pilot operated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and is controlled by a self-actuated auxiliary pressure relief valve.

10 A power actuated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and controlled by a device requiring an external source of energy.

11 A rupture disk device is a nonreclosing pressure relief device actuated by inlet static pressure and designed to function by the bursting of a pressure-containing disk.

NB-7200 OVERPRESSURE PROTECTION REPORT

NB-7210 RESPONSIBILITY FOR REPORT

The provisions intended to meet the requirements of this Article shall be the subject of an Overpressure Protection Report prepared by the Owner or his designee.

[98]

NB-7220 CONTENT OF REPORT

The Overpressure Protection Report shall define the protected systems and the integrated overpressure protection provided. As a minimum, the Report shall include the following:

- (a) identification of specific ASME Section III, Article NB-7000, Edition and Addenda and applicable Code Cases used in the design of the overpressure protection system;
 - (b) drawings showing arrangement of protected systems, including the pressure relief devices;
 - (c) the range of operating conditions, including the effect of discharge piping back pressure;
 - (d) an analysis of the conditions that give rise to the maximum pressure relieving requirements, except when the basis for establishing relieving capacity is the loss of the heat sink of the protected system when the thermal output of the reactor is at its rated power;
 - (e) the relief capacity required to prevent a pressure rise in any component from exceeding the limitations of NB-7300;
 - (f) the operating controls or safety controls of the protected system upon which the anticipated required relief capacity and the maximum pressure and temperature are predicted;
 - (g) the redundancy and independence of the pressure relief devices and their associated pressure sensors and controls employed to preclude a loss of overpressure protection in the event of a failure of any pressure relief device, sensing elements, associated controls, or external power sources;
 - (h) the extent that an individual component can be isolated from the overall system overpressure protection and the analysis of the conditions under which additional individual overpressure protection is necessary;
 - (i) the design secondary pressure, including a justification of the value identified in the Design Specification for pressure relief devices;
 - (j) the analysis of pressure transient conditions, including those associated with the response time of pressure relief valves, taking into account the effect of liquid and two-phase flow;
 - (k) consideration of set pressure and blowdown limitations, taking into account opening pressure tolerances and overpressure of the pressure relief device;
 - (l) consideration of burst pressure tolerance and manufacturing design range of the rupture disk device; and
 - (m) verification that pressure relief devices are not required, if applicable. Verification shall include reference to each component's Design Report and applicable requirements in NB-3000 that demonstrate that the calculated stress intensity levels do not exceed the Service Limits specified in the component Design Specification for all system service loadings.
- [98]**

NB-7230 CERTIFICATION OF REPORT

The Report, after it has been reconciled with the requirements of this Article, shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

NB-7240 REVIEW OF REPORT AFTER INSTALLATION

(a) Any modification of the installation from that used for the preparation of the Overpressure Protection Report shall be reconciled with the Overpressure Protection Report.

(b) Modifications shall be documented in an addendum to the Overpressure Protection Report. The addendum shall contain a copy of the as-built drawing and shall include either:

- (1) a statement that the as-built system meets the requirements of the Overpressure Protection Report; or
- (2) a revision to the Overpressure Protection Report to make it agree with the as-built system; or
- (3) a description of the changes made to the asbuilt system to make it comply with the Overpressure Protection Report.

(c) The addendum shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

NB-7250 FILING OF REPORT

A copy of the Overpressure Protection Report shall be filed at the nuclear power plant site prior to the

Page 255

Inspector signing the Owner's Data Report. The report shall be made available to the Authorized Inspector and regulatory and enforcement authorities having jurisdiction at the nuclear plant site.

NB-7300 RELIEVING CAPACITY

NB-7310 EXPECTED SYSTEM PRESSURE TRANSIENT CONDITIONS¹²

NB-7311 Relieving Capacity of Pressure Relief Devices

(a) The total relieving capacity of the pressure relief devices (certified in accordance with NB-7700 intended for overpressure protection within the scope of this Subsection and credited in conformance with NB-7500 or NB-7600) shall take into account any losses due to flow through piping and other components.

(b) The total relieving capacity shall be sufficient to prevent a rise in pressure of more than 10% above the Design Pressure of any component within the pressure-retaining boundary of the protected system under any expected system pressure transient conditions as summarized in the Overpressure Protection Report (NB-7200).

NB-7312 Relieving Capacity of Pressure Relief Devices Used With Pressure-Reducing Devices

When using pressure-reducing devices, the combined relieving capacity of the pressure relief devices shall be sufficient to meet the requirements of NB-7311, when:

- (a) pressure-reducing devices and their bypass valves are fully open; and
- (b) all discharge paths are blocked on the low pressure side of the pressure-reducing device.

NB-7313 Required Number and Capacity of Pressure Relief Devices

The required relieving capacity for overpressure protection of a system shall be provided by the use of at least two pressure relief devices. In each such group of pressure relief devices when more than one device is used, no device shall have a capacity less than 50% of the device with the largest capacity.

¹² Expected system pressure transient conditions are those associated with normal system transient operation, such as loss of feedwater or loss of load.

NB-7314 Required Number and Capacity of Pressure Relief Devices for Isolatable Components

The required relieving capacity of an isolatable component shall be provided by at least one pressure relief device meeting the requirements of NB-7500 or NB-7600.

NB-7320 UNEXPECTED SYSTEM EXCESS PRESSURE TRANSIENT CONDITIONS¹³

NB-7321 Relieving Capacity of Pressure Relief Devices

- (a) The total relieving capacity of the pressure relief devices (certified in accordance with NB-7700 intended for

overpressure protection within the scope of this Subsection and credited in conformance with NB-7500 or NB-7600) shall take into account any losses due to flow through piping and other components.

(b) The total relieving capacity shall be sufficient to limit the maximum system pressure such that the requirements of (c) are satisfied for each of the components of the system for which overpressure protection is provided, under each of the unexpected system excess pressure transient conditions specified in the Overpressure Protection Report.

(c) The system overpressure established for setting the required total relieving capacity of (b) shall be such that the calculated stress intensity and other design limitations for Service Limit C specified in NB-3000 are not exceeded for each of the components in the protected system.

NB-7400 SET PRESSURES OF PRESSURE RELIEF DEVICES

NB-7410 SET PRESSURE LIMITATIONS FOR EXPECTED SYSTEM PRESSURE TRANSIENT CONDITIONS

13 Unexpected system excess pressure transient conditions are those associated with unusual or abnormal system transients, but still considered to be within the design basis, such as loss of load with failure of reactor scram.

The stamped set pressure of at least one of the pressure relief devices connected to the system shall not be greater than the Design Pressure of any component within the pressure-retaining boundary of the protected system. Additional pressure relief devices may

Page 256

have higher stamped set pressures, but in no case shall these set pressures be such that the total system pressure exceeds the system limitations specified in NB-7310.

NB-7420 SET PRESSURE LIMITATION FOR UNEXPECTED SYSTEM EXCESS PRESSURE TRANSIENT CONDITIONS

The establishment of the stamped set pressure shall take into account the requirements of NB-7320.

NB-7500 OPERATING AND DESIGN REQUIREMENTS FOR PRESSURE RELIEF VALVES

NB-7510 SAFETY, SAFETY RELIEF, AND RELIEF VALVES

NB-7511 General Requirements

NB-7511.1 Spring-Loaded Valves.

Valves shall open automatically by direct action of the fluid pressure as a result of forces acting against a spring.

NB-7511.2 Balanced Valves

(a) Balanced valves, whose operation is independent of back pressure, may be used if means are provided to verify the operability of the balancing device.

(b) Balanced safety valves for steam service shall additionally have a redundant back pressure balancing device.

NB-7511.3 Antisimmer Type Valves.

Valves which are fitted with antisimmer devices that serve to raise the set pressure of the valve during normal operation of the system may be used, provided:

(a) the design is such that the valve opens automatically and discharges its certified capacity at 110% of the system design pressure in the event any item of the auxiliary loading device should fail;

(b) the operating signal and energy source provisions are such that the valve reverts to its normal set pressure in the event of any failure of signal or loss of energy source;

- (c) the auxiliary loading force imposed on such valves does not raise the set pressure of the valve by more than 10%;
- (d) the auxiliary loading force which augments the force exerted by the valve spring is automatically unloaded at a pressure not greater than the set pressure of the valve.

NB-7512 Safety Valve Operating Requirements

NB-7512.1 Antichattering and Lift Requirements.

Safety valves shall be constructed to operate without chattering and to attain rated lift at a pressure which does not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater.

NB-7512.2 Set Pressure Tolerance

(a) The set pressure tolerance plus or minus shall not exceed the following: 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa), 3% for pressures from 70 psi (483 kPa) to 300 psi (2070 kPa), 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) to 1000 psi (6900 kPa), and 1% for pressures over 1000 psi (6900 kPa). The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NB-7200) and in the safety valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) shall be established for each production valve by test. Steam valves shall be tested on steam.

NB-7512.3 Blowdown.

Safety valves shall be adjusted to close after blowing down to a pressure not lower than 95% of the set pressure unless a different percentage is specified in the safety valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (NB-7200). The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

NB-7513 Safety Relief and Relief Valve Operating Requirements

Safety relief and relief valves shall be constructed to attain rated lift at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NB-7513.1 Set Pressure Tolerance

(a) The set pressure tolerance plus or minus from the set pressure of safety relief and relief valves shall not exceed 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa) and 3% for pressure above 70 psi (483 kPa). The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NB-7200) and in the valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) shall be established for each production valve by test. Steam valves shall be tested on steam, air or gas valves on air or gas, and liquid valves on liquid.

Page 257

NB-7513.2 Blowdown.

Safety relief and relief valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250), and the basis for the setting shall be covered in the Overpressure Protection Report (NB-7200). The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

NB-7514 Credited Relieving Capacity

The credited relieving capacity of safety, safety relief, and relief valves shall be based on the certified relieving capacity. In addition, the capacity can be prorated as in NB-7700.

NB-7515 Sealing of Adjustments

Means shall be provided in the design of all valves for sealing all adjustments or access to adjustments which can be made without disassembly of the valve. For a pilot operated pressure relief valve, an additional seal shall be provided to seal the pilot and main valve together. Seals shall be installed by the Certificate Holder at the time of initial adjustment. Seals shall be installed in a manner to prevent changing the adjustment or disassembly of the valve without breaking the seal. The seal shall serve as a means of identifying the Certificate Holder making the initial adjustment.

NB-7520 PILOT OPERATED PRESSURE RELIEF VALVES

NB-7521 General Requirements

Pilot operated pressure relief valves shall operate independently of any external energy source.

NB-7522 Operating Requirements

NB-7522.1 Actuation.

The pilot control device shall be actuated directly by the fluid pressure of the protected system.

NB-7522.2 Response Time.

The Overpressure Protection Report (NB-7200) shall include the effects of divergence between opening (set) and closing (blow down) pressures of the pilot valve and the pressures at which the main valve attains rated lift and closes. These divergences are caused by the inherent time delay (e.g., response time) between the operation of the pilot and the main valve, and the rate of the system pressure change. The limits for response time shall be specified in the valve Design Specification (NCA-3250).

NB-7522.3 Main Valve Operation.

The main valve shall operate in direct response to the pilot control device. The valve shall be constructed to attain rated lift under stable conditions at pressures which do not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater, for steam, and 10% or 3 psi (20.6 kPa), whichever is greater, for air, gas, or liquid service.

NB-7522.4 Sensing Mechanism Integrity.

For other than spring loaded direct acting pilot control devices, means shall be provided to detect failure of the pressure sensing element, such as bellows, when operation of the pilot control device is dependent upon the integrity of a pressure sensing element.

NB-7522.5 Set Pressure Tolerance

(a) The set pressure tolerance shall apply only to the pilot valve.

(b) The set pressure tolerance plus or minus shall not exceed the following: 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa), 3% for pressures over 70 psi (483 kPa) for liquid valves and 3% for pressures over 70 psi (483 kPa) up to and including 300 psi (2070 kPa), 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) up to and including 1000 psi (6900 kPa), and 1% for pressures over 1000 psi (6900 kPa) for steam, air, and gas valves. The set pressure tolerance as stated shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NB-7200) and in the valve Design Specification (NCA-3250).

(c) Conformance with the requirements of (b) above shall be established for each production valve by test. Steam valves shall be tested on steam, air or gas valves on air or gas, and liquid valves on liquid.

NB-7522.6 Blowdown

(a) The blowdown requirements shall only apply to the pilot valve.

(b) Pilot operated valves shall be adjusted to close after blowing down to a pressure not lower than 95% of the set pressure for steam, unless a different percent age is specified in the valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (NB-7200). For all other fluids, pilot operated valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250), and the basis for the setting shall be covered in the Overpressure Protection Report (NB-7200).

Page 258

(c) Conformance with the requirements of (b) above shall be established for each production valve by test or by proration from the Certificate Holder's blowdown test data.

NB-7523 Credited Relieving Capacity

The credited relieving capacity of pilot operated pressure relief valves shall be based on the certified relieving capacity. In addition, the capacity may be prorated as permitted in NB-7700.

NB-7524 Sealing of Adjustments

The sealing requirements of NB-7515 shall apply.

NB-7530 POWER ACTUATED PRESSURE RELIEF VALVES

NB-7531 General Requirements

Power actuated pressure relief valves which depend upon an external energy source, such as electrical, pneumatic, or hydraulic systems, may be used provided the requirements of NB-7530 are met.

NB-7532 Operating Requirements

NB-7532.1 Actuation.

Power actuated pressure relief valves shall be actuated in response to signals from protected system fluid pressure sensing devices.

NB-7532.2 Response Times

(a) The *opening response time* is the time delay between the time the pressure sensor recognizes a predetermined system pressure and the time the power actuated pressure relief valve attains its certified capacity.

(b) The *closing response time* is the time delay between the time the pressure sensor recognizes a predetermined system pressure and the time the power actuated pressure relief valve is fully closed.

(c) The Overpressure Protection Report (NB-7200) shall include an analysis of the effect that opening and closing time responses have on the overpressure protection for the system.

(d) Each production valve shall be tested to verify that the stipulated response time in the Design Specification (NCA-3250) for the valve has been met.

NB-7532.3 Main Valve Operation.

The main valve shall provide rated flow under stable system conditions at pressures which do not exceed the opening actuation pressure by more than 3% or 2 psi (13.8 kPa) whichever is greater for steam, and 10% or 3 psi (20.6 kPa) whichever is greater for air, or gas, or liquid service.

NB-7532.4 Sensors, Controls, and External Energy Sources

(a) The sensors, controls, and external energy sources for valve operation shall have redundancy and independence at least equal to that required for the control and safety protection systems associated with the system being protected.

(b) The pressure sensors shall be capable of controlling the opening actuation pressure to within a tolerance of $\pm 1\%$ when the automatic control is in use.

(c) When automatic control is in use, the valve closing actuation pressure shall be controlled to a pressure not lower than 95% of the opening actuation pressure unless a different percentage is specified in the Design Specification (NCA-3250) and the basis for the closing actuation pressure is covered in the Overpressure Protection Report (NB-7200).

(d) Conformance with requirements of (b) and (c) above shall be established through test by the owner or his designee. Steam valves shall be tested on steam, gas or air valves on gas or air, and liquid valves on liquid.

NB-7533 Certified Relieving Capacity

The power actuated pressure relief valve certified relieving capacity and the proration of capacity shall be as determined by NB-7700.

NB-7534 Credited Relieving Capacity

NB-7534.1 Expected System Pressure Transient Conditions.

For expected system pressure transient conditions, the relieving capacity with which these valves are credited shall be not more than:

(a) the certified relieving capacity of the smaller one when two valves are installed;

(b) one-half of total certified relieving capacity when three or more valves are installed.

NB-7534.2 Unexpected System Excess Pressure Transient Conditions.

For unexpected system excess pressure transient conditions, the credited relieving capacity with which these valves are credited shall be not more than:

(a) the certified relieving capacity of the valve with the smaller certified capacity when two valves are installed;

(b) the certified relieving capacity of all except the valve with the largest certified capacity when three through ten valves are installed;

Page 259

(c) the certified relieving capacity of all except two valves of the largest certified capacity when more than ten valves are installed.

NB-7535 Sealing of Adjustments

Means shall be provided for the sealing of all adjustments which affect valve operation. Seals shall be installed by the owner or his designee at the time of setting. Seals shall be installed in such a manner as to prevent changing the adjustment without breaking the seal and shall serve as a means of identifying the organization responsible for making the adjustment.

NB-7540 SAFETY VALVES AND PILOT OPERATED PRESSURE RELIEF VALVES WITH AUXILIARY ACTUATING DEVICES

Safety valves and pilot operated pressure relief valves with auxiliary actuating devices which operate independently of the self-actuating mechanism of the valve may be used provided the requirements of NB-7510 or NB-7520, as applicable, are met, except as modified below.

NB-7541 Construction

(a) The construction shall be such that the valve opens automatically by direct action of the fluid at a pressure not higher than the valve set pressure and relieves at the certified relieving capacity in the event of failure of any essential part of the valve's auxiliary devices.

(b) The construction of the auxiliary actuating device shall be such that loss of electrical power or loss of auxiliary actuating pressure to the device will not prevent the valve from closing.

NB-7542 Expected System Pressure Transient Conditions

For expected system pressure transient conditions, credit for capacity (NB-7545) can be taken for valves opening at the setpoint of the auxiliary actuating device in accordance with (a) and (b) below.

(a) When two valves are installed, the valve of the smaller certified capacity is credited with opening at the setpoint of the auxiliary actuating device. The valve with the larger certified capacity is credited with opening at the valve set pressure.

(b) For groups of more than two valves (all of the same certified capacity), half the valves in a group containing an even number of valves or the number of valves in the group minus one divided by two in a group containing an odd number of valves are credited with opening at the setpoint of the auxiliary actuating device. The remainder of the valves in the group are credited with opening at the valve set pressure.

NB-7543 Unexpected System Excess Pressure Transient Conditions

For unexpected system excess pressure transient conditions, credit for capacity may be taken for valves opening at the setpoint of the auxiliary actuating device in accordance with the following.

(a) When two valves are installed, the valve with the smaller certified capacity may be credited with opening at the setpoint of the auxiliary actuating device. The valve with the larger certified capacity shall be credited with opening at the valve set pressure.

(b) When three through ten valves are installed, credit may be given for opening at the setpoint of the auxiliary actuating device for all valves except one with the largest certified capacity. The valve assumed not to open at the setpoint of the auxiliary actuating device shall be credited with opening at the valve set pressure.

(c) When more than ten valves are installed, credit may be given for opening at the setpoint of the auxiliary actuating device for all valves except for two of the largest certified capacity. The two valves assumed not to open at the setpoint of the auxiliary actuating device shall be credited with opening at the valve set pressure.

NB-7544 Auxiliary Device Sensors and Controls

The sensors, controls, and external energy sources for the auxiliary actuating device shall comply with the requirements of NB-7532.

NB-7545 Credited Relieving Capacity

The relieving capacities with which these valves are credited shall be:

(a) for valves credited with opening at auxiliary actuating device setpoint, the capacity at the lower relieving pressure as determined by the rules of NB-7700 (this shall specifically include the 90% of average tested capacity inherent in the Code certification procedure);

(b) for valves credited with opening at the valve set pressure, the certified capacity as determined by the rules of NB-7700.

Page 260

NB-7546 Response Time

For valves credited with opening at the auxiliary actuating device setpoint, consideration shall be given to the time delay between the signal to open and achieving the fully opened position and the time delay between the signal to close and achieving the fully closed position.

NB-7600 NONRECLOSING PRESSURE RELIEF DEVICES

NB-7610 RUPTURE DISK DEVICES

Rupture disk devices certified in accordance with NB-7720 are subject to the following:

- (a) rupture disk devices shall not be used as the sole pressure relief devices;
- (b) rupture disk devices used in conjunction with pressure relief valves shall be located only on the outlet side of the valve (NB-7623).

NB-7611 Burst Pressure Tolerance

The burst pressure tolerance at the specified disk temperature¹⁴ shall not exceed ± 2 psi (± 13.8 kPa) for stamped burst pressure up to and including 40 psi (276 kPa) and $\pm 5\%$ for stamped burst pressure above 40 psi (276 kPa) as established by the rules of NB-7613, unless other values have been established in the Design Specification and are covered in the Overpressure Protection Report.

NB-7612 Tests to Establish Stamped Burst Pressure

(a) Every rupture disk shall have a stamped burst pressure established by rules of NB-7611 within a manufacturing design range¹⁵ at a specified disk temperature, and shall be stamped with a lot number.

(b) Each lot of rupture disks shall be tested in accordance with one of the following methods. All tests of disks for a given lot shall be made in a holder of the same form and pressure area dimensions as that being used in service.

14 The specified disk temperature supplied to the rupture disk manufacturer shall be the expected temperature of the disk when the disk is expected to burst.

15 The manufacturing design range is a range of pressure within which the stamped burst pressure must fall. This range is included in the Design Specification and the Overpressure Protection Report.

(1) At least two sample rupture disks from each lot of rupture disks¹⁶ shall be burst at the specified disk temperature. The stamped burst pressure shall be determined so that the sample rupture disk burst pressures are within the tolerance specified by NB-7611.

(2) At least four sample rupture disks, but not less than 5%, from each lot of rupture disks shall be burst at four different temperatures distributed over the applicable temperature range for which the disks will be used. This data shall be used to establish a smooth curve of burst pressure versus temperature for the lot of disks. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in NB-7611.

The value for the stamped burst pressure shall be established from the curve for a specified disk temperature.

(3) For prebulged solid metal disks or graphite disks only, at least four sample rupture disks using one size of disk from each lot of material shall be burst at four different temperatures, distributed over the applicable temperature range for which this material will be used. This data shall be used to establish a smooth curve of burst pressure versus temperature for the lot of material. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in NB-7611.

At least two disks from each lot of disks, made from this lot of material and of the same size as those to be used, shall be burst at the ambient temperature to establish the room rating of the lot of disks. The curve shall be used to establish the stamped rating at the specified disk temperature for the lot of disks.

NB-7620 INSTALLATION

NB-7621 Provisions for Venting or Draining

When a rupture disk is used in conjunction with a pressure relief valve, the space between the rupture disk and the pressure relief valve shall be vented and/or drained to controlled thermal dissipation or discharge storage systems.

NB-7622 System Obstructions

Piping and other components downstream of the rupture disk shall be constructed so that bursting of the rupture disk will not impair the function of the pressure relief valve by the release of rupture disk material.

NB-7623 Rupture Disk Devices at the Outlet Side of Pressure Relief Valves

A rupture disk device may be installed at the outlet side of pressure relief valves if the following provisions are met:

- (a) the set pressure of the valve is independent of back pressure, or the set pressure of the valve plus the stamped burst pressure of the rupture disk plus any pressure in the outlet piping does not exceed the limits of NB-7400;
- (b) the relieving capacity meets the requirements of NB-7300;
- (c) the stamped burst pressure of the rupture disk at the specified disk temperature plus any pressure in the outlet piping from the rupture disk device shall not exceed the secondary Design Pressure of the pressure relief valve and the Design Pressure of any pipe or fittings between the valve and the rupture disk device. However, in no case shall the stamped burst pressure of the rupture disk at the operating temperature plus any pressure in the outlet piping from the rupture disk device exceed the limits of NB-7400;
- (d) the opening provided through the rupture disk device after burst is sufficient for the pressure relief valve to flow at its certified capacity.

NB-7700 CERTIFICATION

NB-7710 RESPONSIBILITY FOR CERTIFICATION OF PRESSURE RELIEF VALVES

The Certificate Holder shall be responsible for having the relieving capacity of its valves certified as prescribed in this Subarticle.

NB-7720 RESPONSIBILITY FOR CERTIFICATION OF NONRECLOSING PRESSURE RELIEF DEVICES

The rupture disk Manufacturer shall certify the stamped burst pressure of the disk.

NB-7730 CAPACITY CERTIFICATION PRESSURE RELIEF VALVES - COMPRESSIBLE FLUIDS

NB-7731 General Requirements

NB-7731.1 Capacity Certification

- (a) Capacity certification procedures shall be as required in NB-7732 through NB-7737.
- (b) For steam at pressures over 1500 psig and up to 3200 psig, the value of K used to determine the certified relieving capacity shall be multiplied by:

$$(0.1906P - 1000)/(0.2292P - 1061)$$

where

$$P = \text{set pressure, psig}$$

This correction is also applicable to the certified relieving capacity as determined by the curve method.

NB-7731.2 Test Media

- (a) Capacity certification tests of pressure relief valves for steam service shall be conducted with dry saturated steam. For test purposes, the limits of 98% minimum quality and 20°F (11°C) maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

(b) Capacity certification tests for pressure relief valves for air and gas service shall be conducted with air, gas, or dry saturated steam.

(c) Demonstration of function tests shall be performed using the same fluid media to which the pressure relief valve is expected to be exposed in service.

NB-7731.3 Test Pressure

(a) Capacity certification tests of pressure relief valves (except safety relief valves) for steam service shall be conducted at a pressure which does not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater, except as permitted in (b).

(b) Capacity certification tests of safety relief valves (NB-7513) for steam service shall be conducted at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

(c) Capacity certification tests of pressure relief valves for air or gas shall be conducted at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NB-7731.4 Blowdown.

Valves having an adjustable blowdown construction shall be adjusted prior to capacity certification testing so that the blowdown does not exceed 5% of the set pressure.

NB-7731.5 Drawings.

Prior to capacity certification and demonstration of function tests, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and all test results to the ASME designee for review and acceptance.

NB-7731.6 Design Changes.

When changes are made in the design of a pressure relief valve which affect the

Page 262

flow path, lift, or performance characteristics, new tests shall be performed in accordance with this Subarticle.

NB-7732 Flow Model Test Method

NB-7732.1 Flow Capacity.

When test facility limitations make it impossible to perform tests of the full-scale pressure relief valves, flow models of three different sizes may be utilized as a basis for capacity certification. Such flow models shall be sized consistent with the capabilities of the accepted test laboratory where the tests will be conducted and shall accurately model those features which affect flow capacity, such as orifice size, valve lift, and internal flow configuration. The test models need not be functional pressure relief valves, provided that other tests are conducted to demonstrate proper function of the valve design as prescribed in NB-7732.2. The relieving capacity of valve designs certified by the use of flow models shall be established by the coefficient of discharge method similar to that outlined in NB-7734.1 and NB-7734.2. The certified relieving capacity of all sizes and pressures of a given design for which the value of K has been established, based on flow model tests in accordance with the method of NB-7734, shall not exceed the value calculated by the appropriate formula in NB-7734.2 multiplied by the coefficient K .

NB-7732.2 Demonstration of Function

(a) The function of three valves of the design to be certified shall be demonstrated by test. The three valves selected shall envelop the largest and smallest combination of inlet size and orifice size of the specific design. Such tests may be performed in conjunction with the capacity certification tests outlined above or as separate tests using production valves.

(b) These tests shall be conducted at a place meeting the requirements of NB-7739 to demonstrate to the satisfaction of an ASME designee that the valves will meet the operating requirements specified in NB-7500 and achieve full lift under

the conditions established in (c).

(c) The NV Certificate Holder shall specify the range of pressures, temperatures, and other fluid conditions for which the valves are to be tested. The range shall be sufficient to cover all expected operating fluid conditions. Additionally, tests shall include the range of inlet pressure losses and discharge back pressure conditions for which the valves are expected to be used.

(d) The NV Certificate Holder shall document in the remarks section on the Data Report Form NV-1 that the requirements of this subparagraph have been met.

NB-7733 Slope Method

(a) For pressure relief valves of a specific design, four valves of each combination inlet size and orifice size shall be tested. These four valves shall be set at pressures that will cover the appropriate range of pressures for which the valves are to be used or within the range of the authorized test facility.

(b) The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as the measured capacity divided by the absolute inlet pressure. If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following a test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the flow rating pressure, psia.

(c) In addition, demonstration of function tests shall be conducted as prescribed in NB-7732.2.

NB-7734 Coefficient of Discharge Method

A coefficient K may be established for a specific pressure relief valve design according to the procedure given in the following subparagraphs.

NB-7734.1 Number of Valves to Be Tested.

For each design, at least three valves for each of three different sizes shall be submitted for test. Each valve of a given size shall be set at a different pressure.

NB-7734.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each pressure relief valve to determine its lift, opening, blowdown pressures, and capacity in terms of the fluid used in the test. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test, and Theoretical Flow is calculated by the following formula:

For test with dry saturated steam:

$$W_T = 51.5AP$$

Pressures over 1500 psig and up to 3200 psig the value of W_T , calculated by the above equation, shall be corrected by being multiplied by the following factor:

$$\frac{(0.1906P - 1000)}{(0.2292P - 1061)}$$

For test with air:

$$W_T = 356AP \sqrt{\frac{M}{T}}$$

For test with gas:

$$W_T = CAP \sqrt{\frac{M}{ZT}}$$

where

A	= actual discharge area through the valve at developed lift, sq in.
C	= constant for gas or vapor which is a function of the ratio of specific heats, k
k	= c_p/c_v (see Fig. XVIII-1110-1)
M	= molecular weight
P	= (set pressure $\times$ 1.03) plus atmospheric pressure, psia, or set pressure plus 2 psi plus atmospheric pressure, whichever is greater, for test pressures determined by NB-7731.3(a) = (set pressure $\times$ 1.10) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater, for test pressures determined by NB-7731.1(b) or (c)
T	= absolute temperature at inlet, $^{\circ}\text{F} + 460$
W_T	= theoretical flow, lb/hr
Z	= compressibility factor corresponding to P and T

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90, and their product shall be taken as the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NB-7734.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design, for which the value of K has been established

under the provisions of NB-7734.2 and which are manufactured subsequently, shall not exceed the value calculated by the appropriate formula multiplied by the coefficient K .

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_D , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

NB-7734.4 Demonstration of Function.

Tests shall be conducted as prescribed in NB-7732.2.

NB-7735 Single Valve Method

NB-7735.1 Valve Capacity Within Test Facility Limits

(a) When a single valve is to be capacity tested, the certified capacity may be based on three separate tests associated with each set pressure for which capacity certification is required.

(b) The certified capacity associated with each set pressure shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity associated with each set pressure shall be cause for rejection of the test. The reason for the failure shall be determined, and the test repeated.

(c) Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

NB-7735.2 Valve Capacity in Excess of Test Facility Limits.

For valves whose capacity exceeds that of the test facility, the certified capacity may be based on a flow coefficient K (NB-7734.2) determined from either blocked open flow tests or flow model tests, provided the orifice area is such that choked flow conditions are obtained. The certified capacity shall be calculated as directed in NB-7734.3.

NB-7735.3 Valve Demonstration of Function.

Tests shall be conducted as prescribed in NB-7732.2, except that one valve of the specific inlet size, orifice size,

Page 264

and specific design shall be tested. Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to meet the three valve requirement of NB-7732.2.

NB-7736 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve design is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in NB-7733 multiplied by the prorated relieving pressure (psia); or

(2) the prorated capacity shall be calculated using the appropriate formula from NB-7734.2 [where P is the prorated relieving pressure (psia) multiplied by the coefficient K].

NB-7737 Capacity Conversions

The relieving capacity of pressure relief valves for fluids other than the fluid used for certification shall be determined by the method of conversion given in Appendix XVIII-1000, except that valves for steam service shall be tested on steam.

NB-7738 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁷

17 Valve capacities published in "Pressure Relief Device Certification." This publication may be obtained from the National Board of Boiler and Pressure and Pressure Vessel Inspectors, 1055 Crupper Avenue, Columbus, OH 43229.

NB-7739 Laboratory Acceptance of Demonstration of Function Tests

The NV Certificate Holder shall assure that the tests are conducted at a place where the testing facilities, methods, and procedures provide for sufficient testing capacity and range of fluid properties so that the testing requirements of NB-7732.2 are met.

NB-7740 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - INCOMPRESSIBLE FLUIDS

NB-7741 General Requirements

NB-7741.1 Capacity Certification.

Capacity certification procedures shall be as required in NB-7742 through NB-7745.

NB-7741.2 Test Medium.

The test medium to be used for capacity certification shall be water at a temperature between 40°F (4°C) and 125°F (52°C). Demonstration of function tests shall be performed on water at temperatures representative of those to which the pressure relief valve is expected to be exposed in service.

NB-7741.3 Test Pressure.

The capacity certification tests shall be conducted at pressures which do not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater. Demonstration of function tests shall be performed at pressures representative of those to which the pressure relief valve is expected to be exposed in service.

NB-7741.4 Blowdown.

Blowdown shall be recorded at the time of the capacity certification and demonstration of function tests.

NB-7741.5 Drawings.

Prior to capacity certification and demonstration of function tests, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and all test results to the ASME designee for review and acceptance.

NB-7741.6 Design Changes.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Subarticle shall be performed.

NB-7742 Slope Method

(a) Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall

be set at pressures which cover the appropriate range of pressures for which the valves are to be used, or within the range

of the test facility. The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as the measured capacity divided by the square root of the difference between the flow rating pressure and the valve discharge pressure. If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following a test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the square root of the difference between the flow rating pressure and the valve discharge pressure.

(b) Demonstration of function tests shall be conducted as specified in NB-7732.2.

NB-7743 Coefficient of Discharge Method

Instead of individual capacity tests or the capacity curve method, a coefficient K may be established for a specific pressure relief valve design in accordance with the following subparagraphs.

NB-7743.1 Number of Valves to Be Tested.

For each design, three valves for each of three different sizes shall be tested, for a total of nine valves. Each valve of a given size shall be set at a different pressure.

NB-7743.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity, in terms of pounds of water per hour. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test, and Theoretical Flow is calculated by the following formula:

For tests with water:

$$W_t = 2407A \sqrt{(P - P_d)W}$$

where

A	= actual minimum discharge area through the valve at developed lift, sq in.
P	= (set pressure $\times 1.10$) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater, flow rating pressure, psia
P_d	= pressure at discharge from valve, psia
W	= density of water at valve inlet conditions, lb/cu ft
W_t	= Theoretical Flow, lb/hr

The average of the coefficients of discharge K_D of the tests shall be multiplied by 0.90, and the product shall be taken as the coefficient K of the design. The coefficient of the design shall not be greater than 0.896 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NB-7743.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design for which the value of K has been established under the provisions of NB-7743.2 shall not exceed the value calculated by the theoretical formula above multiplied by the coefficient K .

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_D , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

NB-7743.4 Demonstration of Function.

Tests shall be conducted as specified in NB-7732.2.

NB-7744 Single Valve Method

(a) When a single valve at a single pressure is to be capacity tested, the capacity rating may be based

Page 266

on three separate tests of the single valve at the specified set pressure.

(b) The certified capacity rating of the valve shall not exceed 90% of the average established by the tests. Failure of the individual test capacities to fall within 5% of the average capacity shall be cause for rejection of the test. The reason for the failure shall be determined and the tests repeated.

(c) Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

(d) Demonstration of function tests shall be conducted as specified in NB-7732.2 except one valve of the specific inlet size, orifice size, and that specific design shall be tested. Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable, to meet the three valve requirement of NB-7732.2.

NB-7745 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to acceptance of the ASME Boiler and Pressure Vessel Committee upon recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.

NB-7746 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve design is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in NB-7742 multiplied by the prorated relieving pressure (psia); or

(2) the prorated capacity shall be calculated using the appropriate formula from NB-7743.2 [where P is the prorated relieving pressure (psia) multiplied by the coefficient K].

NB-7747 Capacity Conversions

The rated pressure relieving capacity of pressure relief valves for liquids other than the liquids used for certification shall be determined by the method of conversion given in Appendix XVIII-1000. This conversion is not valid for liquid flashing valve operating conditions.

NB-7748 Laboratory Acceptance of Demonstration of Function Tests

The NV Certificate Holder shall assure that the tests are conducted at a place where the testing facilities, methods, and procedures provide for sufficient testing capacity and range of fluid properties so that the requirements of NB-7732.2 are met.

NB-7800 MARKING, STAMPING, AND DATA REPORTS

NB-7810 PRESSURE RELIEF VALVES

NB-7811 Marking and Stamping

Each pressure relief valve shall be plainly marked by the Certificate Holder with the required data below in such a way that the marking will not be obliterated in service. The data shall be in characters not less than $\frac{3}{32}$ in. (2.4 mm) high. The marking shall be placed on the valve or on a nameplate securely fastened to the valve. The Code Symbol shall be stamped on the valve or nameplate, but the other required data may be stamped, etched, impressed, or cast. The marking shall include the following:

(a) the name, or an acceptable abbreviation, of the Certificate Holder;

(b) Certificate Holder's design or type number;

(c) size ____ (NPS, the nominal pipe size) of the valve inlet;

(d) set pressure ____ psi;

(e) certified capacity and overpressure in percent or psi:

(1) lb/hr of saturated steam for valves certified on steam; or

(2) scfm (standard cubic feet per minute) at 60°F and 14.7 psia of air for valves certified on air or gas; or

(3) gal/min of water at 70°F for valves certified on water.

Page 267

(f) applicable official Code Symbol Stamp, as shown in Table NCA-8100-1. In addition to the above, each pressure relief valve shall have a separate nameplate attached to the component that includes the marking requirements of NCA-8220 and NB-3593.2.

NB-7812 Report Form for Pressure Relief Valves

A Data Report Form NV-1 shall be filled out and signed by the Certificate Holder, and signed by the Inspector for each safety and safety relief valve stamped with the Code NV Symbol.

NB-7820 RUPTURE DISK DEVICES

18 In lieu of marking all of the listed items on the flange or tab of each rupture disk, the marking may consist of a Manufacturer's coding number sufficient to identify each rupture disk with a certificate or tab which includes the required information and is supplied with each lot of rupture disks.

NB-7821 Rupture Disks

Every rupture disk shall be plainly marked by the manufacturer in such a way that the marking will not be obliterated in service. The rupture disk marking may be placed on the flange of the rupture disk or on a metal tab permanently attached thereto.¹⁸ The marking shall include the following:

- (a) the name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number
- (c) lot number
- (d) size ____ in.
- (e) stamped bursting pressure ____ psi
- (f) specified disk temperature ____ °F
- (g) capacity ____ lb/hr of saturated steam or ____ standard cu ft of air (60°F and 14.7 psia)/min
- (h) year built

NB-7822 Disk Holders (If Used)

Rupture disk holders shall be marked with the following:

- (a) the name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number
- (c) size ____ in.
- (d) year built
- (e) serial number

NB-7830 CERTIFICATE OF AUTHORIZATION TO USE CODE SYMBOL STAMP

Each pressure relief valve within the scope of this Article shall be constructed by a Manufacturer possessing a Code NV Symbol Stamp and valid Certificate of Authorization. Pressure relief valves shall have the Code NV Symbol applied in accordance with the rules of NB-8100.

quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
 (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits that indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

**IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE
ADDENDA DISTRIBUTION SCHEDULE**

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998

(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor

prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

Page viii

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all

material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NC-1000

ARTICLE NC-1000 INTRODUCTION

Page 1

Page 3

NC-1100 SCOPE

(a) Subsection NC contains rules for the material, design, fabrication, examination, testing, overpressure relief, marking, stamping, and preparation of reports by the Certificate Holder for items which are intended to conform to the requirements for Class 2 construction.

(b) The rules of Subsection NC cover the strength and pressure integrity of items the failure of which would violate the pressure retaining boundary. The rules cover load stresses but do not cover deterioration which may occur in service as a result of corrosion, radiation effects, or instability of materials. NCA-1130 further limits the rules of this Subsection.

(c) Subsection NC does not contain rules to cover all details of construction of Class 2 vessels and storage tanks. Where complete details are not provided in this Subsection, it is intended that the N Certificate Holder, subject to the approval of the Owner or his designee and acceptance by the Inspector, shall provide details of construction which will be consistent with those provided by the rules of this Subsection.

NC-1120 TEMPERATURE LIMITS

Vessels are to be designed using the standard design method in NC-3300 or the alternative design rules of NC-3200, which allows the use of analysis with the higher design stress intensity values of Tables 2A, 2B, and 4, Section II, Part D, Subpart 1.

NC-1130 BOUNDARIES OF JURISDICTION APPLICABLE TO THIS SUBSECTION

NC-1131 Boundary of Components

The Design Specification shall define the boundary of a component to which piping or another component is attached. The boundary shall not be closer to a vessel, tank, pump, or valve than:

- (a) the first circumferential joint in welded connections (the connecting weld shall be considered part of the piping);
- (b) the face of the first flange in bolted connections (the bolts shall be considered part of the piping);
- (c) the first threaded joint in screwed connections.

NC-1132 Boundary Between Components and Attachments

NC-1132.1 Attachments

(a) An *attachment* is an element in contact with or connected to the inside or outside of the pressure retaining portion of a component which may have either a pressure retaining or nonpressure-retaining function and either a structural or nonstructural function.

(b) Attachments with a pressure retaining function include items such as stiffeners and branch or vessel opening reinforcement.

(c) Attachments with a nonpressure-retaining function include items such as valve guides, thermal sleeves, turning vanes, and component support load path items such as vessel saddles, support and shear lugs, brackets, pipe clamps,

vanes, and component support load path items such as vessel saddles, support and shear lugs, brackets, pipe clamps, trunnions, and skirts.

(d) Attachments with a structural function (structural attachments) perform a pressure retaining function or are in the component support load path.

(e) Attachments with a nonstructural function (nonstructural attachments) do not perform a pressure retaining function nor are they in the component support load path. Nonstructural attachments include items such as nameplates, insulation supports, and locating and lifting lugs.

NC-1132.2 Jurisdictional Boundary.

The jurisdictional boundary between a pressure retaining component and an attachment defined in the Design Specification shall not be any closer to the pressure retaining portion of the component than as defined in (a) through (g)

Page 4

below. Figures NC-1132.2-1 through NC-1132.2-3 are provided as an aid in defining the boundary and construction requirements of this Subsection.

(a) Attachments cast or forged with the component and weld buildup on the component surface shall be considered part of the component.

(b) Attachments, welds, and fasteners having a pressure retaining function shall be considered part of the component.

(c) Except as provided in (d) and (e) below, the boundary between a pressure retaining component and an attachment not having a pressure retaining function shall be at the surface of the component.

(d) The first connecting weld of a nonpressure-retaining structural attachment to a component shall be considered part of the component unless the weld is more than $2t$ from the pressure retaining portion of the component, where t is the nominal thickness of the pressure retaining material. Beyond $2t$ from the pressure retaining portion of the component, the first weld shall be considered part of the attachment.

(e) The first connecting weld of a welded nonstructural attachment to a component shall be considered part of the attachment. At or within $2t$ from the pressure retaining portion of the component the first connecting weld shall conform to NC-4330.

(f) Mechanical fasteners used to connect a nonpressure-retaining attachment to the component shall be considered part of the attachment.

(g) The boundary may be located further from the pressure retaining portion of the component than as defined in (a) through (f) above when specified in the Design Specification.

Page 5

Page 6

- ① Component shall conform to Subsection NC.
- ② Pressure retaining portion of the component.
- ③ Jurisdictional boundary (heavy line).
- ④ Cast or forged attachment or weld buildup shall conform to Subsection NC.
- ⑤ Beyond $2t$ from the pressure retaining portion of the component, the design rules of NF-3000 may be used as a substitute for the design rules of NC-3000.
- ⑥ At or within $2t$ from the pressure retaining portion of the component, the first connecting weld shall conform to Subsection NC.
- ⑦ Beyond $2t$ from the pressure retaining portion of the component or beyond the first connecting weld, the attachment shall conform to Subsection NF [Note (1)].
- ⑧ Bearing, clamped, or fastened attachment shall conform to Subsection NF [Note (1)].
- ⑨ Attachment connection shall conform to Subsection NF [Note (1)].
- ⑩ At or within $2t$ from the pressure retaining portion of the component, the interaction effects of the attachment shall be considered in accordance with NC-3135.
- ⑪ Drilled holes shall conform to Subsection NC.

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

NOTE:

(1) If the attachment is an intervening element [NF-1110(c)], material, design and connections, as appropriate, are outside Code jurisdiction.

American Society Of Mechanical Engineers
SEC III D1 NC-2000

NC-2100 GENERAL REQUIREMENTS FOR MATERIAL

[98]

NC-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-1220. The term *Material Organization* is defined in NCA-9000.

(b) The term *pressure retaining materials* as used in this Subsection applies to vessel shells, heads, and nozzles; pipes, tubes, and fittings; valve bodies, bonnets, and disks; pump casings and covers; and bolting which joins pressure retaining items.

(c) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:

(1) *plate* - the thickness is the dimension of the short transverse direction;

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness);

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length;

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness. For axial length > 2 in. (51 mm), the radial thickness is the nominal thickness.

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness.

(3) *Castings*

(a) Thickness t for fracture toughness testing is defined as the nominal pipe wall thickness of the connecting piping.

(b) Thickness t for heat treatment purposes is defined as the thickness of the pressure retaining wall of the casting excluding flanges and sections designated by the designer as nonpressure retaining.

[98]

NC-2120 PRESSURE RETAINING MATERIAL

NC-2121 Permitted Material Specifications

(a) Pressure retaining material shall conform to the requirements of one of the specifications for materials given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 and to all of the requirements of this Article which apply to the product form in which the material is used. Attachments which perform a pressure retaining function shall be pressure retaining material. For vessels which are designed in accordance with NC-3200, the materials shall be restricted to those materials listed in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 and to the following clad product specifications, provided they are composed of materials listed in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1:

SA-263 Specification for Corrosion-Resisting Chromium-Steel Clad Plate, Sheet, and Strip

SA-264 Specification for Corrosion-Resisting Chromium-Nickel Steel Clad Plate, Sheet, and Strip

SA-265 Specification for Nickel and Nickel-Base Alloy Clad Steel Plate

(b) The requirements of this Article do not apply to material for items not associated with the pressure retaining function of a component such as shafts, stems, trim, spray nozzles, bearings, bushings, springs, wear plates, nor to seals, packing, gaskets, valve seats, and ceramic insulating materials and special alloys used as seal materials in electrical penetration assemblies.

(c) Material made to specifications other than those specified in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 may be used for the following applications:

- (1) *Safety valve disks and nozzles* - when the nozzles are internally contained by the external body structure
- (2) *Control valve disks and cages* - when the valves function for flow control only
- (3) *Line valve disks in valves* - whose inlet connections are NPS 2 (DN 50) and smaller.

Page 14

(d) Material for line fittings, 1 in. nominal pipe size and less, may be of material made to specifications other than those listed in Section II, Part D, Subpart 1, provided that the fittings are in conformance with the requirements of NC-3671.4 and the material is determined to be adequate for the service conditions by the piping system designer.

(e) Welding and brazing materials used in manufacture of items shall comply with an SFA specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to materials used as backing rings or backing strips in welded joints.

(f) The requirements of this Article do not apply to hard surfacing or corrosion resistant weld metal overlay which is 10% or less of the thickness of the base material (NC-3122).

NC-2122 Special Requirements Conflicting With Permitted Material Specifications

Special requirements stipulated in this Article shall apply in lieu of the requirements of the material specifications wherever the special requirements conflict with the material specification requirements [NCA-3856]. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Required nondestructive examinations shall be performed as specified for each product form in NC-2500. Any examination, repair, test, or treatment required by the material specification or by this Article may be performed by the Material Manufacturer or the Certificate Holder as provided in NC-4121.1. Any hydrostatic or pneumatic pressure test required by a material specification need not be performed, provided the material is identified as not having been pressure tested and it is subsequently pressure tested in accordance with NC-6114, except where the location of the material in the component or the installation would prevent performing any nondestructive examination required by the material specification to be performed subsequent to the hydrostatic or pneumatic test.

NC-2124 Material Size Ranges and Tolerances

(a) Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in this Subsection. In those specifications in which chemical composition or mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range [NCA-3856].

(b) Plate material shall be ordered not thinner than the design thickness. Components, except for piping, made of plate furnished with an undertolerance of not more than the lesser value of 0.01 in. or 6% of the ordered thickness, may be used at the full design pressure for the thickness ordered. If the specification to which the plate is ordered allows a greater undertolerance, the ordered thickness of the material shall be sufficiently greater than the design thickness so that the thickness of the material furnished is not more than the lesser of 0.01 in. or 6% under the design thickness.

(c) If pipe or tube is ordered by its nominal wall thickness, the manufacturing undertolerance on wall thickness shall be taken into account. The manufacturing undertolerances are given in the several pipe and tube specifications listed in the applicable Tables in Section II, Part D, Subpart 1. After the minimum wall thickness is determined (NC-3641.1), it shall be increased by an amount sufficient to provide for the manufacturing undertolerance allowed in the pipe or tube specification.

NC-2125 Material in Combination¹

A component may be designed and constructed of any combination of materials permitted in NC-2000, provided the applicable rules are followed and the requirements of Section IX for welding dissimilar metals are met.

NC-2126 Integrally Finned Tubes

Integrally finned tubes may be made from tubes that conform to one of the specifications for tubes listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 and to all of the special requirements of this Article which apply to that product form. In addition, the following requirements shall apply.

(a) The requirements of NC-2550 shall be met by the tube before finning.

1 Because of the different thermal coefficients of expansion of dissimilar materials, caution shall be exercised in construction under the provisions of this paragraph in order to avoid difficulties in service under extreme temperature conditions, or with unusual restraint such as may occur at points of stress concentration and also because of metallurgical changes occurring at high temperatures.

Page 15

(b) The tubes after finning shall conform to the applicable heat treatment requirements of the basic material specification.

(c) The allowable stress values shall be those given in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3 for the tube material from which the finned tube is made.

(d) After finning, each tube shall be subjected to one of the following tests:

(1) an internal pneumatic pressure test at not less than 250 psi without evidence of leakage; the test method, such as immersion of the tube under water during the test, shall permit visual detection of any leakage;

(2) an individual tube hydrostatic test at 1.25 times the Design Pressure which permits complete examination of the tube for leakage.

(e) A visual examination shall be performed after finning. Material having discontinuities, such as laps, seams, or cracks, is unacceptable.

NC-2128 Bolting Material

(a) Material for bolts and studs shall conform to the requirements of one of the specifications listed in Table 3, Section II, Part D, Subpart 1. Material for nuts shall conform to SA-194 or to the requirements of one of the specifications for nuts or bolting listed in Table 3, Section II, Part D, Subpart 1. Refer to Table 4, Section II, Part D, Subpart 1 for bolting material for vessels designed to the requirements of NC-3200.

(b) The use of washers is optional. When used, they shall be made of wrought material with mechanical properties compatible with the nuts with which they are to be employed.

NC-2130 CERTIFICATION OF MATERIAL

All materials used in the construction of components shall be certified as required in NCA-3862 and NCA-3861. Certified Material Test Reports are required for pressure retaining material except as provided by NCA-3861. A Certificate of Compliance may be provided in lieu of a Certified Material Test Report for all other material. Copies of all Certified Material Test Reports and Certificates of Compliance applicable to material used in a component shall be furnished with the material.

NC-2140 WELDING MATERIALS

For the requirements governing the materials to be used for welding, see NC-2400.

NC-2150 MATERIAL IDENTIFICATION

The identification of pressure retaining material shall meet the requirements of NCA-3856. Material for small items shall be controlled during manufacture and installation of the component so that they are identifiable as acceptable material at all times. Welding and brazing materials shall be controlled during the repair of material and the manufacture and installation so that they are identifiable as acceptable until the material is actually consumed in the process (NC-4122).

NC-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material.

NC-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steels, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the component at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment.

NC-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature by thermocouples in contact with the material or attached to blocks in contact with the material or by calibrated pyrometric instruments. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

Page 16

NC-2190 NONPRESSURE-RETAINING MATERIAL

(a) Material in the component support load path and not performing a pressure retaining function (see NC-1130) welded to pressure retaining material shall meet the requirements of NF-2000.

(b) Material not performing a pressure retaining function and not in the component support load path (nonstructural attachments) welded at or within $2t$ of the pressure retaining portion of the component need not comply with NC-2000 or NF-2000 provided the requirements of NC-4430 are met.

(c) Structural steel rolled shapes, which are permitted by this Subsection to be furnished with a Certificate of Compliance, may be repaired by welding using the welders, documentation, and examination requirements specified in SA-6.

NC-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

NC-2210 HEAT TREATMENT REQUIREMENTS

NC-2211 Test Coupon Heat Treatment for Ferritic Material²

Where ferritic steel material is subjected to heat treatment during fabrication or installation of a component, the material used for the tensile and impact test specimens shall be heat treated in the same manner as the component, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. (51 mm) or less are not required to be so heat treated where nominal thickness for flanges refers to the wall thickness at the weld joint to the pipe or component. The Certificate Holder shall provide the Material Manufacturer with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material, and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

2 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NC-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

NC-2212.1 Cooling Rates.

Where ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing those materials shall be cooled at a rate similar to and no faster than the main body of the material except in the case of certain forgings and castings (NC-2223.3 and NC-2226.4). This rule shall apply for coupons taken directly

from the material as well as for separate test coupons representing the material, and one of the general procedures described in NC-2212.2 or one of the specific procedures described in NC-2220 shall be used for each product form.

NC-2212.2 General Procedures.

One of the general procedures in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with NC-2220. Further specific details of the methods to be used shall be the obligation of the Material Manufacturer and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material that matches the cooling rate of the main body of the product at the region midway between midthickness and the surface ($\frac{1}{4}t$) and no nearer any heat treated edge than a distance equal to the nominal thickness t being quenched within 25°F (14°C) and 20 sec at all temperatures after cooling begins from the austenitizing temperature.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material, provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in NC-2220 are used, faster cooling rates at the edges may be compensated for by:

(1) taking the test specimens at least t from a quenched edge, where t equals the material thickness;

(2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed; or

(3) using thermal barriers or insulation at the edge where specimens are to be removed.

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

Page 17

NC-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

NC-2221 General Requirements

The procedure for obtaining test specimens for quenched and tempered material is related to the product form. Coupon and specimen location shall be as required by the material specification, except as stated in the following paragraphs of this Subarticle. References to dimensions signify nominal values.

NC-2222 Plates

NC-2222.1 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from any heat treated edge, where t is the nominal thickness of the material.

NC-2222.2 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the component material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with NC-2212.2, the dimensions of the coupon shall be not less than $3t \times 3t \times t$, where t is the nominal material thickness.

NC-2223 Forgings

NC-2223.1

NC-2223.1 Forgings With 2 in. (51 mm) Maximum Thickness.

For forgings with a maximum thickness of 2 in., the coupons shall be taken so that specimens shall have their longitudinal axes at the midplane of the thickness or the center of the cross section and with the midlength of the specimens at least 2 in. from any second surface.

NC-2223.2 Forgings With Thickness Exceeding 2 in. (51 mm)

For forgings exceeding a thickness of 2 in. (51 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ of the maximum heat treated thickness from any surface and with the midlength of the specimens at least t from any second surface. This is normally referred to as $\frac{1}{4}t \times t$, where t is the maximum heat treated thickness. A thermal buffer may be used to achieve the above conditions [NC-2212.2(c)(3)] unless cooling rates applicable to the bulk forgings are simulated in accordance with NC-2212.2.

NC-2223.3 Very Thick and Complex Forgings.

Test coupons for forgings which are both very thick and complex, such as contour nozzles, thick tubesheets, flanges, nozzles, and other complex forgings that are contour shaped or machined to essentially the finished product configuration prior to heat treatment, may be removed from prolongations or other stock provided on the product. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface, equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat treatment, and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall not be nearer than $\frac{3}{4}$ in. (19 mm) to any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. (38 mm) from any heat treated surface.

NC-2223.4 Coupons From Separately Produced Test Forgings.

Test coupons representing forgings from one heat and one heat treatment lot may be taken from a separately forged piece under the conditions given in (a) through (e) below.

(a) The separate test forging shall be of the same heat of material and shall be subjected to substantially the same reduction and working as the production forging it represents.

(b) The separate test forging shall be heat treated in the same furnace charge and under the same conditions as the production forging.

(c) The separate test forging shall be of the same nominal thickness as the production forging.

(d) Test coupons for simple forgings shall be taken so that specimens shall have their longitudinal axes at the region midway between midthickness and the surface and with the midlength of the specimens no nearer any heat treated edge than a distance equal to the forging thickness, except when the thickness-length ratio of the production forging does not permit, in which case a production forging shall be used as the test forging and the midlength of the specimens shall be at the midlength of the test forging.

(e) Test coupons for complex forgings shall be taken in accordance with NC-2223.3.

NC-2223.5 Test Specimens for Forgings.

When test specimens for forgings are to be taken under the

Page 18

applicable specification, the Inspector shall have the option of witnessing the selection, placing an identifying stamp on them, and witnessing the testing of these specimens.

NC-2224 Bars and Bolting Material

NC-2224.1 Bars With 2 in. (51 mm) Maximum Thickness.

For bars with diameters or thicknesses 2 in. (51 mm) or less, the coupons shall be taken so that specimens shall have

their longitudinal axes on a line representing the center of the thickness and with the midlength of the specimens at least one diameter or thickness from a heat treated end.

NC-2224.2 Bars With Thicknesses Exceeding 2 in. (51 mm).

For bars with diameters or thicknesses over 2 in. (51 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface and with the midlength of the specimens at least t from a heat treated end, where t is either the bar diameter or thickness.

NC-2224.3 Bolting Material.

For bolting material, the coupons shall be taken in conformance with the applicable material specification and with the midlength of the specimen at least one diameter or thickness from a heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NC-2225 Tubular Products

NC-2225.1 Tubular Products With 2 in. (51 mm) Maximum Thickness.

For tubular products with 2 in. (51 mm) maximum wall thickness, the coupons shall be taken so that specimens shall have their longitudinal axes on a surface midway between the outside and inside surfaces and with the midlength of the specimens at least one wall thickness from a heat treated end.

NC-2225.2 Tubular Products Exceeding 2 in. (51 mm) Nominal Thickness.

For tubular products with nominal wall thicknesses exceeding 2 in. (51 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside surface and with the midlength of the specimens at least one wall thickness from a heat treated end.

NC-2225.3 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of NC-2223.4 shall be met.

NC-2226 Tensile Test Specimen Location (for Quenched and Tempered Ferritic Steel Castings)

NOTE: Users of this requirement should note that the hardenability of some grades may limit the usable section size.

(a) This section applies only to quenched-and-tempered ferritic steel castings with a thickness t exceeding 2 in. Where t is the thickness of the pressure retaining wall of the casting excluding flanges and sections designated by the designer as nonpressure-retaining. The order, inquiry, and drawing shall designate what the thickness t is for the casting.

(b) One of the following shall apply.

(1) The longitudinal centering of the thickness of the tension test specimen shall be taken at least $\frac{1}{4}t$ from the t dimension surface. For cylindrical castings, the longitudinal center line of the specimens shall be taken at least $\frac{1}{4}t$ from the outside or inside surface, and the gage length at least t from the as-heat treated end.

(2) Where separately cast test coupons are used, their dimensions shall be not less than $3t \times 3t \times T$, and each specimen cut from it shall meet the requirements of (b). The test coupon shall be of the same heat of steel and shall receive substantially the same casting practices as the production casting it represents. (Centrifugal castings may be represented by statically cast coupons.) The test coupon shall be heat treated under the same conditions as the production casting(s). The t dimension of the test coupon shall be the same maximum thickness t as defined in (a) above. Where separate test blocks require reheat treatment, thermal buffers in accordance with (b) may be used.

(3) Where specimens are to be removed from the body of the casting, a steel, thermal buffer pad $1t \times 1t \times$ at least $3t$ shall

be joined to the casting surface by a partial penetration weld completely sealing the buffered surface prior to the heat treatment process. The test specimens shall be removed from the casting in a location adjacent to the center third of the buffer pad. They shall be located at a minimum distance of $\frac{1}{2}$ in. from the buffered surface and $\frac{1}{4}$ in. from the other heat treated surfaces.

(4) Where specimens are to be removed from the body of the casting, thermal insulation or other thermal barriers shall be used during the heat treatment process

Page 19

adjacent to the casting edge where specimens are to be removed. It shall be demonstrated that the cooling rate of the test specimen is no faster than that of specimens taken by the method described in (b)(1). This information shall be included in the test reports.

(5) Where castings are cast or machined to essentially the finished product configuration prior to heat treatment, the test specimens shall be removed from a casting prolongation or other stock on the product at a location below the nearest heat treated surface indicated on the order. The specimens shall be located with their longitudinal axes a distance below the nearest heat treated surface equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest heat treated surface, and with their midlength a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the test specimens shall be no nearer than $\frac{1}{4}$ in. (6 mm) to a heat treated surface and the midlength shall be at least $1\frac{1}{2}$ in. (38 mm) from a second heat treated surface. The component manufacturer shall specify the surfaces of the finished product subjected to high tensile stress in service.

NC-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

NC-2310 MATERIAL TO BE IMPACT TESTED

NC-2311 Material for Which Impact Testing Is Required

(a) Pressure retaining material shall be impact tested in accordance with the requirements of NC-2330, except that impact testing of materials described in (1) through (9) below is not a requirement of this Subsection:

(1) material with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) and less where thicknesses shall be taken as defined in (a) through (e) below:

(a) for pumps, valves, and fittings, use the largest nominal pipe wall thickness of the connecting pipes;

(b) for vessels and tanks, use the nominal thickness of the shell or head, as applicable;

(c) for nozzles or parts welded to vessels, use the lesser of the vessel shell thickness to which the item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections;

(d) for flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub;

(e) for integral fittings used to attach process piping to the containment vessel (Fig. NE-1120-1), use the larger nominal thickness of the pipe connections.

(2) bolting, including studs, nuts, and bolts, with a nominal size of 1 in. (25 mm) or less;

(3) bar with a nominal cross-sectional area which does not exceed 1 sq in. (645 mm²);

(4) all thicknesses of material for pipe, tube, fittings, pumps, and valves with a nominal pipe size 6 in. (152 mm) diameter and smaller;

(5) material for pumps, valves, and fittings with all pipe connections of $\frac{5}{8}$ in. (16 mm) nominal wall thickness and less;

(6) austenitic stainless steels;

(7) nonferrous materials;

(8) materials listed in Table NC-2311(a)-1 for which the listed value of T_{NDT}^3 is lower than the Lowest Service Temperature⁴ (LST) by an amount established by the rules in Appendix R. This exemption does not exempt either the weld metal (NC-2430) or the welding procedure qualification (NC-4335) from impact testing.

- (9) materials for components for which the Lowest Service Temperature exceeds 150°F (66°C).
- (b) The Design Specification shall state the Lowest Service Temperature for the component.
- (c) Drop weight tests are not required for the martensitic high alloy chromium (Series 4XX) steels and precipitation-hardening steels listed in Section II, Part D, Subpart 1, Table 1A. The other requirements of NC-2331 and NC-2332 apply for these steels. For nominal wall thicknesses greater than 2½ in. (64 mm), the required C_v values shall be 40 mils lateral expansion.

NC-2320 IMPACT TEST PROCEDURES

NC-2321 Types of Tests

NC-2321.1 Drop Weight Tests.

The drop weight test, when required, shall be performed in accordance with ASTM E 208-91. Specimen types P-1, P-2, or P-3 may be used. When drop weight tests are performed to meet the requirements of NC-2300, the test temperature and the results shall be reported on the Certified Material Test Report.

³ T_{NDT} - temperature at or above the nil-ductility transition temperature NDT (ASTM E 208-85); T_{NDT} is 10°F below the temperature at which at least two specimens show no-break performance.

⁴ Lowest Service Temperature (LST) is the minimum temperature of the fluid retained by the component or, alternatively, the calculated minimum metal temperature whenever the pressure within the component exceeds 20% of the preoperational system hydrostatic test pressure.

SA-508, Class 2	Q & T	+40

NOTES:

- (1) These materials are exempt from toughness testing when LST- T_{NDT} is satisfied in accordance with the rules established in Appendix R.
- (2) Material Condition letters refer to:
N – normalize
Q & T – quench and temper
HR – hot rolled
- (3) These values for T_{NDT} were established from data on heavy section steel (thickness greater than 2½ in.). Values for sections less than 2½ in. thick are held constant until additional data are obtained.
- (4) T_{NDT} – temperature at or above nil-ductility transition temperature NDT (ASTM E 208-91); T_{NDT} is 10°F below the temperature at which at least two specimens show no-break performance.
- (5) Materials made to a fine grain melting practice.

TABLE NC-2311(a)-1 EXEMPTIONS FROM IMPACT TESTING UNDER NC-2311(a)(8)

NC-2321.2 Charpy V-Notch Tests.

The Charpy V-notch test (C_V), when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of NC-2330 shall be reported in the Certified Material Test Report.

NC-2322 Test Specimens

NC-2322.1 Location of Test Specimens.

Impact test specimens shall be removed from a depth within the material that is at least as far from the material surface as that specified for tensile test specimens in the material specification. For bolting, the C_V impact test specimens shall be taken with the longitudinal axis of the specimen located at least one-half radius or 1 in. (25 mm) below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimen shall be at least one diameter or thickness from the heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NC-2322.2 Orientation of Impact Test Specimens

(a) Specimens for C_V impact tests shall be oriented as required in NC-2200 for the tensile test specimen or, alternatively, the orientation may be in the direction of maximum stress. The notch of the C_V specimen shall be normal to the surface of the material.

(b) Specimens for drop weight tests may have their axes oriented in any direction.

NC-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS

NC-2331 Pressure Retaining Material Test Methods and Temperature

(a) Pressure retaining material shall be impact tested in accordance with one of the test methods indicated below:

(1) Charpy V-notch testing at or below the Lowest Service Metal Temperature⁵⁶

(2) drop weight testing to show that the Lowest Service Metal Temperature⁵ ($LST - T_{NDT}^3$) is satisfied in accordance with the rules established in Appendix R.

NC-2332 Specific Test Methods and Acceptance Standards for Pressure Retaining Material for Tests Based on Lowest Service Metal Temperatures

5 The Lowest Service Metal Temperature shall be the lowest temperature which the metal may experience in service while the plant is in operation and shall be established by appropriate calculations based on atmospheric ambient conditions, the insulation or enclosure provided, and the minimum temperature which will be maintained inside the vessel during the plant operation.

6 The requirements for impact testing of the heat affected zone (NC-4335.2) may result in reduced impact test temperatures for the base material.

7 For pumps, valves, and fittings, use the nominal pipe wall thickness of the connecting pipe. For vessels use the lesser of:

(a) the maximum radial thickness of the item, exclusive of integral butt welded projections;

(b) the vessel shell thickness to which the item is welded;

(c) the maximum shell thickness associated with the item for flat heads, tubesheets, or flanges.

NC-2332.1 Pressure Retaining Material Other Than Bolting With 2½ in. (64 mm) Maximum Thickness.⁷

Except as limited in NC-4335, apply one of the methods of NC-2331(a) to test: base material; the base

material, the heat affected zone, and weld metal for the weld procedure qualification tests of NC-4335; and the weld metal for NC-2431. The impact test results shall meet one of the acceptance standards applicable to the specified test method.

TABLE NC-2332.1-1
REQUIRED C_v LATERAL EXPANSION VALUES^{1,2} FOR
PRESSURE RETAINING MATERIAL OTHER THAN
BOLTING

Nominal Wall Thickness, in. [Note (3)]	Lateral Expansion, mils	
	Average of 3	Lowest 1 of 3
$\frac{5}{8}$ in. or less [Note (4)]	...	...
Over $\frac{5}{8}$ in. to 1 in., incl.	20	15
Over 1 in. to $1\frac{1}{2}$ in., incl.	25	20
Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in., incl.	35	30
Over $2\frac{1}{2}$ in. [Note (5)]	45	40

NOTES:

- (1) Where weld metal tests of NC-2400 are made to these requirements, the impact lateral expansion shall conform to the requirements of either of the base materials being joined.
- (2) Where two base materials having different required lateral expansion values are joined, the weld metal lateral expansion requirements of NC-4330 shall conform to the requirements of either of the base materials.
- (3) For pumps, valves, and fittings, use the nominal pipe wall thickness of the connecting pipe. For vessels use the least of:
 - (a) the maximum radial thickness of the item exclusive of integral butt welded projections;
 - (b) the vessel shell thickness to which the item is welded;
 - (c) the maximum shell thickness associated with the item for flat heads, tubesheets, or flanges.
- (4) No test required.
- (5) For use with NC-2332.2(b).

TABLE NC-2332.1-1 REQUIRED C_V LATERAL EXPANSION VALUES^{1,2} FOR PRESSURE RETAINING MATERIAL OTHER THAN BOLTING

(a) *Charpy V-Notch Testing for Lateral Expansion Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NC-2332.1-1.

(b) *Charpy V-Notch Testing for Absorbed Energy Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NC-2332.1-2.

(c) *Drop Weight Testing.* An acceptance test shall consist of at least two no-break specimens as described in ASTM E 208-85.

NC-2332.2 Pressure Retaining Material Other Than Bolting With Thickness ⁷ Exceeding 2½ in.(64 mm)

(a) The base material, and the weld procedure qualification weld metal tests of NC-4335, shall be tested by the drop weight method as specified in NC-2321.1 and NC-2331(a)(2).

(b) Except as limited in NC-4335, apply one of the methods of NC-2331(a) to test: the base material and the heat affected zone of the weld procedure qualification tests for NC-4335; and the weld metal for NC-2431.

(c) The acceptance standards shall be as given in NC-2332.1(a), (b), or (c), as applicable.

NC-2332.3 Bolting Material.

For bolting material, including nuts, studs, and bolts, a Charpy V-notch test shall be performed. The tests shall be performed at or below the Lowest Service Metal Temperature, and all three specimens shall meet the requirements of Table NC-2332.3-1.

NC-2340 NUMBER OF IMPACT TESTS REQUIRED

NC-2341 Plates

One test shall be made from each plate as heat treated. Where plates are furnished in the nonheattreated condition and qualified by heat treated test specimens, one test shall be made for each plate as rolled. The term *as-rolled* refers to the plate rolled from a slab or directly from an ingot, not to its heat treated condition.

NC-2342 Forgings and Castings

(a) Where an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment charge.

(b) When heat treatment is performed in a continuous-type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment charge shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2,000 lb (907 kg).

(c) One test shall be made for each forging or casting of 1,000 lb to 10,000 lb (454 kg to 4540 kg).

(d) As an alternative to NC-2342(c), a separate test forging or casting may be used to represent forgings or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

**TABLE NC-2332.1-2
REQUIRED C_v ENERGY VALUES¹ FOR PRESSURE RETAINING MATERIAL
OTHER THAN BOLTING**

Nominal Wall Thickness, in. [Note (3)]	Energy, ft-lb for Base [Note (2)] Materials of Specified Minimum Yield Strength, ksi					
	55 ksi or below		Over 55 ksi to 75 ksi, incl.		Over 75 ksi to 105 ksi, incl.	
	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3
5/8 in. or less [Note (4)]	...	...	...	...	...	...
Over 5/8 in. to 1 in., incl.	20	15	25	20	30	25
Over 1 in. to 1 1/2 in., incl.	25	20	30	25	35	30
Over 1 1/2 in. to 2 1/2 in., incl.	35	30	40	35	45	40
Over 2 1/2 in. [Note (5)]	45	40	50	45	55	50

NOTES:

- (1) Where weld metal tests of NC-2400 are made to these requirements, the impact energy shall conform to the requirements of either of the base materials being joined.
- (2) Where two base materials having different required energy values are joined, the weld metal impact energy requirements of the procedure qualification tests of NC-4330 shall conform to the requirements of either of the base materials.
- (3) For pumps, valves, and fittings, use the nominal pipe wall thickness of the connecting pipe. For vessels use the least of:
 - (a) the maximum radial thickness of the item exclusive of integral butt welded projections;
 - (b) the vessel shell thickness to which the item is welded;
 - (c) the maximum shell thickness associated with the item for flat heads, tubesheets, or flanges.
- (4) No test required.
- (5) For use with NC-2332.2(b).

TABLE NC-2332.1-2 REQUIRED C_v ENERGY VALUES¹ FOR PRESSURE RETAINING MATERIAL OTHER THAN BOLTING

**TABLE NC-2332.3-1
REQUIRED C_v VALUES FOR BOLTING MATERIAL
TESTED IN ACCORDANCE WITH NC-2332.3**

Nominal Diameter, in.	Lateral Expansion, mils	Absorbed Energy, ft-lb
1 or less	No test required	No test required
Over 1 through 4	25	No requirements
Over 4	25	45

TABLE NC-2332.3-1 REQUIRED C_v VALUES FOR BOLTING MATERIAL TESTED IN ACCORDANCE WITH

NC-2332.3

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V-notch and one test for drop weights. The location of drop weight or C_v test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg. apart.

(f) As an alternative to NC-2342(e) for static castings, a separately cast coupon [NC-2226(b)(2)] may be used; one test shall be made for Charpy V-notch and one test for drop weight.

NC-2343 Bars

One test shall be made for each lot of bars with a cross-sectional area greater than 1 sq in. (645 mm²) where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed 6000 lb (2720 kg).

NC-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification, but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than $\frac{1}{4}$ in. (6 mm); such a lot shall be in a single heat treatment load or in the same continuous run in a continuous furnace controlled within a 50°F (28°C) range and equipped with recording pyrometers.

NC-2345 Bolting Material

One test shall be made for each lot of material where a lot is defined as one heat of material heat treated

Page 23

in one charge or as one continuous operation, not to exceed the following:

$1\frac{3}{4}$ in. diameter and less	1,500 lb
Over $1\frac{3}{4}$ in. to $2\frac{1}{2}$ in. diameter	3,000 lb
Over $2\frac{1}{2}$ in. to 5 in. diameter	6,000 lb
Over 5 in. diameter	10,000 lb

NC-2350 RETESTS

NC-2351 Retests for Material Other Than Bolting

(a) For Charpy V-notch tests required by NC-2330, one retest at the same temperature may be conducted, provided:

(1) the average value of the test results meets the average of three requirements specified in Table NC-2332.1-1 or Table NC-2332.1-2, as applicable;

(2) not more than one specimen per test is below the lowest one of three requirements specified in Table NC-2332.1-1 or Table NC-2332.1-2, as applicable;

(3) the specimen not meeting the requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the lowest one of three requirements specified in Table NC-2332.1-1 or Table NC-2332.1-2, as applicable.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall be equal to or greater than the average of three requirements specified in Table NC-2332.1-1 or Table NC-2332.1-2, as applicable.

NC-2352 Retests for Bolting Material

(a) For Charpy V-notch tests required by NC-2330, one retest at the same temperature may be conducted, provided:

- (1) not more than one specimen per test is below the acceptance requirements;
 - (2) the specimen not meeting the acceptance requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the acceptance requirements.
- (b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall meet the specified acceptance requirements.

[98]

NC-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency specified in (a) or (b) below.

(a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.

(b) C_v impact test machines shall be calibrated and the results recorded to meet the requirements of NCA-3868. The calibrations shall be performed at least once per year using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

[98]

NC-2400 WELDING MATERIAL

NC-2410 GENERAL REQUIREMENTS

(a) All welding material used in the construction and repair of components or material, except welding material used for cladding or hard surfacing, shall conform to the requirements of the welding material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in NC-2150.

(b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable:

- (1) welding process;
- (2) SFA specification and classification;
- (3) other identification if no SFA specification applies;
- (4) minimum tensile strength [NC-2431.1(e)] in either the as-welded or heat treated condition, or both [NC-2431.1(c)];
- (5) drop weight test for material in either the as-welded or heat treated condition, or both (NC-2332);
- (6) Charpy V-notch test for material as-welded, or heat treated, or both (NC-2331); the test temperature and the lateral expansion or the absorbed energy shall be provided;
- (7) the preheat and interpass temperatures to be used during welding of the test coupon [NC-2431.1(c)];
- (8) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [NC-2431.1(c)];
- (9) elements for which chemical analysis is required per the SFA specification or WPS, and NC-2432;
- (10) minimum delta ferrite (NC-2433).

Page 24

NC-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electrogas welding) processes (Section

IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes and dry blend of supplementary powdered filler metal and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electroslag flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by NC-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities to which the liquid binders may be added to produce a number of wet mixes.

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch (a) or dry blend (b) and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (453,600 kg), from chemically controlled tube, wire, or strip and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding materials is coded for identification and traceable to the production period, the shift, line, and the analysis range of both the mix and the rod, tube, or strip used to make the electrode.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with a maximum of one splice per coil that has been chemically analyzed to assure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed except that those coils which are splice free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with of SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a heat may be defined as either the material produced from the same melt of metal or the material produced from one type and size of wire when produced in a continuous period (not to exceed 24 hr and not to exceed 100,000 lb) from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

(2) Carbon, manganese, silicon, and other intentionally added elements shall be identified to ensure that the material conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A *lot of submerged arc or electroslag flux* is defined as the quantity of flux produced from the same combination of raw materials under one production schedule.

(h) A *dry blend of supplementary powdered filler metal* is defined as one or more mixes of material produced in a

and traceable to the production period, the shift, and the mixing vessel. A chemically controlled mix of powdered filler metal is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

NC-2430 WELD METAL TESTS

NC-2431 Mechanical Properties Test

Tensile and impact tests shall be made in accordance with this paragraph, of welding materials which are used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below.

- (a) austenitic stainless steel and nonferrous welding material used to join the listed P-Numbers;
- (b) consumable inserts (backing filler material);
- (c) welding material used for GTAW root deposits with a maximum of two layers;
- (d) welding material to be used for the welding of base materials exempted from impact testing by NC-2311(a)(1) through (a)(7) or NC-2311(a)(9) shall also be exempted from the impact testing required by this paragraph.

NC-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below, using each process with which the weld material will be used in production welding.

- (a) Test coupons shall be of sufficient size and thickness such that the test specimens required herein can be removed.
- (b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such a manner as to substantially eliminate the influence of the base material on the results of the tests. Weld metal to be used with the electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure Specifications (WPS) for production welding, Section IX, QW-201.1. The base material shall conform to the requirements of Section IX, QW-403.1 or QW-403.4, as applicable.
- (c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures that will be used in production welding. Coupons shall be tested in the as-welded condition, or they shall be tested in the applicable postweld heat treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time⁸ shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the component. In addition, weld coupons for weld metal to be used with the electroslag process, which are tested in the as-welded condition or following a postweld heat treatment within the holding temperature ranges of Table NC-4622.1-1 or NC-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment, which will include heating the coupon to a temperature above the Holding Temperature Range of Table NC-4622.1-1 for the type of material being tested, shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.
- (d) Regardless of the welding process or welding material being tested, the tensile specimens, and the C_v impact specimens when required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. Drop weight impact test specimens, where required, shall be oriented so that the longitudinal axis is transverse to the weld, with the notch in the weld face or in a plane parallel to the weld face. For impact specimen preparation and testing, the applicable parts of NC-2321.1 and NC-2321.2 shall apply. The longitudinal

axis of the specimen shall be at a minimum depth of $\frac{1}{4}t$ from a surface, where t is the thickness of the test weld.

(e) One all-weld-metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. Where base materials of different specifications are to be welded, the tensile strength requirements shall conform to the specified minimum tensile strength requirement of either of the base material specifications.

8 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

Page 26

(f) Impact specimens of the weld metal shall be tested where impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the parts of NC-2331 or NC-2332 applicable to the base material. Where different requirements exist for the two base materials, the weld metal may conform to either of the requirements for either base material.

NC-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in NC-2431.1, tensile and impact tests may be made in accordance with this subparagraph where they are required for mild and low alloy steel covered electrodes. The material combinations to require weld material testing, as listed in NC-2431, shall apply for this option. The limitations and testing under this option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in SFA-5.1 or SFA-5.5.

(b) The assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of impact specimens required by NC-2331 or NC-2332, as applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA specification for the classification of electrode being tested. Coupons shall be tested in the as-welded condition and also the postweld heat treated condition. The postweld heat treatment temperatures shall be in accordance with Table NC-4622.1-1 for the applicable P-Number equivalent. The time at postweld heat treatment temperature shall be 8 hr (this qualifies postweld heat treatments of 10 hr or less). When the postweld heat treatment of the production weld exceeds 10 hr or the PWHT temperature is other than that required, the general test of NC-2431.1 shall be used.

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of SFA-5.1 or SFA-5.5, as applicable. Drop weight impact test specimens, where required, shall be located and oriented as specified in NC-2431.1(d).

(e) One all-weld-metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirement of the SFA specification for the applicable electrode classification.

(f) The requirements of NC-2431.1(f) shall be applicable to the impact testing.

**TABLE NC-2432.1-1
SAMPLING OF WELDING MATERIALS FOR
CHEMICAL ANALYSIS**

	GTAW/PAW	GMAW	All other Processes
A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE NC-2432.1-1 SAMPLING OF WELDING MATERIALS FOR CHEMICAL ANALYSIS

NC-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with NC-2420 and as required by the following subparagraphs.

NC-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this subparagraph and Table NC-2432.1-1, and the results shall conform to NC-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the welding material specification specifies percentage composition limits for analysis, it shall state that the specified limits apply for the filler metal analysis, the undiluted weld deposit analysis, or the *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in

specification, the sample shall be removed from a weld pad, groove, or other test weld⁹ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specifications that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the mechanical properties test coupon. Where a chemical analysis is required for a welding material which does not have a mechanical properties test requirement, a chemical analysis test coupon shall be prepared as required by NC-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of NC-2431.1(c) do not apply.

(d) The alternate method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion resistant overlay cladding shall require a test weld made in accordance with the essential variables of the welding procedure specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform to QW-214.3 for the minimum thickness for which the Welding Procedure Specification is qualified.

NC-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a), (b), and (c) below.

(a) Welding material of ferrous alloy A-No. 8 (Section IX, QW-442) shall be analyzed for the elements listed in Table NC-2432.2-1 and for any other elements specified either in the welding material specification referenced by the Welding Procedure Specification or in the Welding Procedure Specification.

⁹ The methods given in the Appendix of SFA 5.9, Specification for Corrosion-Resisting Chromium and Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements, these composition limits of the Welding Procedure Specification shall apply for acceptability.

TABLE NC-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

Cr-Ni stainless materials	C, Cr, Mo, Ni, Mn, Si, Cb
------------------------------	------------------------------

TABLE NC-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

(c) The results of the chemical analysis shall be reported in accordance with NCA-3867. Elements listed in Table NC-2432.2-1 but not specified in the welding material specification or Welding Procedure Specification shall be reported for information only.

NC-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4 Type 16-8-2 or A-No. 8 weld filler metal to be used for weld metal cladding.

NC-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of the chemical analysis of NC-2432 in conjunction with Fig. NC-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS-A 4.2-91.

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NC-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number.

NC-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN (Ferrite Number). The results of the delta ferrite determination shall be included in the Certified Material Test Report of NC-2130 or NC-4120.

Page 28

Page 29

FIG. NC-2433.1-1 WELD METAL DELTA FERRITE CONTENT

FIG. NC-2433.1-1 WELD METAL DELTA FERRITE CONTENT

NC-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding materials shall be maintained. Precautions shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

NC-2500 EXAMINATION AND REPAIR OF PRESSURE RETAINING MATERIAL

NC-2510 PRESSURE RETAINING MATERIAL

Pressure retaining material shall be examined and repaired in accordance with the material specification and as otherwise required by this Subarticle. Pressure retaining material for ASME B16.34 Special Class category valves (NC-3513) shall be examined and repaired in accordance with the requirements therein and as otherwise required by this Subarticle. If the examination and repair requirements of this Subarticle either duplicate or exceed the ASME B16.34 requirements, then only the requirements of this Subarticle need to be met. Size exclusions or quality factor pressure ratings of this Subarticle shall not be applied so as to reduce the examination requirements of ASME B16.34 for Special Class category valves.

NC-2530 EXAMINATION AND REPAIR OF PLATE

NC-2531 Required Examination

Plates shall be examined in accordance with the requirements of the material specification.

NC-2537 Time of Examination

Acceptance examinations shall be performed at the time of manufacture as required in (a) through (c) below.

(a) Examinations required by the material specification shall be performed at the time of manufacture as specified in the material specification.

(b) Radiographic examination of repair welds, when required, may be performed prior to any required postweld heat treatment.

(c) Magnetic particle or liquid penetrant examination of repair welds shall be performed after any required postweld heat treatment, except for P-No. 1 material, which may be examined before or after any required postweld heat treatment.

NC-2538 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) and (b) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface.

(b) When the elimination of the defect reduces the thickness of the section below the minimum required by the design, the material shall be repaired in accordance with NC-2539.

NC-2539 Repair by Welding

The Material Manufacturer may repair by welding materials from which defects have been removed, provided the depth of the repair cavity does not exceed one-third of the nominal thickness and the requirements of the following subparagraphs are met. Prior approval of the Certificate Holder shall be obtained for the repair of plates to be used in the manufacture of vessels.

NC-2539.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of acceptable limit by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (NC-4211.1).

NC-2539.2

The welding procedure and welders or welding operators shall be qualified in accordance with NC-4000 and Section IX.

NC-2539.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NC-2539.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (NC-2545) or by the liquid penetrant method (NC-2546). In addition, when the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, the repair weld shall be radiographed in accordance with and to the applicable acceptance standards of NC-5320. The penetrometer shall be based upon the section thickness of the repaired area.

NC-2539.5 Heat Treatment After Repairs.

The product shall be heat treated after repair in accordance with the requirements of NC-4620.

NC-2539.6 Material Report Describing Defects and Repair.

Each defect repair that is required to be radiographed

Page 30

shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and a report of the results of the examinations, including radiographic film.

NC-2540 EXAMINATION AND REPAIR OF FORGINGS AND BARS

NC-2541 Required Examinations

Forgings and bars shall be examined in accordance with the requirements of the material specification, except when magnetic particle or liquid penetrant examination is specifically required by the rules of this Subsection, in which case the examination shall conform to the requirements of NC-2545 or NC-2546, as applicable.

NC-2545 Magnetic Particle Examination

NC-2545.1 Examination Procedure.

The procedure for magnetic particle examination shall be in accordance with the methods of Section V, Article 7.

NC-2545.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication in excess of the NC-2545.3 acceptance standards which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are those which result from imperfections. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width. Indications resulting from nonmetallic inclusions are not considered relevant indications.

NC-2545.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NC-2546 Liquid Penetrant Examinations

NC-2546.1 Examination Procedure.

The procedure for liquid penetrant examination shall be in accordance with the methods of Section V, Article 6.

NC-2546.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities, such as may occur from machining marks or surface conditions, may produce similar indications which are not relevant.

(b) Any indication in excess of the NC-2546.3 acceptance standards, which is believed to be nonrelevant, shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are those which result from imperfections. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NC-2546.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick,

greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NC-2547 Time of Examination

The requirements for time of examination shall be the same as stated in NC-2537.

NC-2548 Elimination of Surface Defects

Elimination of surface defects shall be made in accordance with NC-2538.

NC-2549 Repair by Welding

Repair by welding shall be performed in accordance with NC-2539, except that the depth of repair that is permitted is not limited.

NC-2550 EXAMINATION AND REPAIR OF SEAMLESS AND WELDED (WITHOUT FILLER METAL) TUBULAR PRODUCTS AND FITTINGS

NC-2551 Required Examination

(a) Wrought seamless tubular products and fittings shall comply with the requirements of NC-2557, NC-2558, and NC-2559, in addition to the basic material specification.

(b) Welded (without filler metal) tubular products, except copper and nickel alloy pipe and tubing, shall comply with the requirements of NC-2557, NC-2558, and NC-2559; in addition, the welds shall be examined by one of the following methods:

- (1) ultrasonic examination in accordance with NC-2552;
- (2) eddy current examination in accordance with NC-2554;
- (3) radiographic examination in accordance with NC-2553.

(c) Copper alloy and nickel alloy seamless pipe and tubing shall comply with the requirements of NC-2558, in addition to the basic material specification.

NC-2552 Ultrasonic Examination¹⁰

NC-2552.1 Examination Procedure for Welds in Pipe and Tubing

(a) *Circumferential Direction - $6\frac{3}{4}$ in. (171 mm) O.D. and Smaller.* The welds in pipe and tubing shall be examined in two circumferential directions. The procedure for ultrasonic examination of pipe and tubing in the circumferential direction shall be in accordance with ASTM E 213-79, Standard Method for Ultrasonic Examination of Pipe and Tubing for Longitudinal Discontinuities, and the requirements of this paragraph. The procedure shall provide a sensitivity which will consistently detect defects that produce indications equal to or greater than the indications produced by standard defects included in the reference specimens specified in NC-2552.3.

(b) *Pipe and Tubing Larger Than $6\frac{3}{4}$ in. (171 mm) O.D.* The welds in pipe and tubing shall be examined in two circumferential directions. The procedure for ultrasonic examination of pipe and tubing larger than $6\frac{3}{4}$ in. (171 mm) O.D. shall be in accordance either with the requirements of SA-388 for angle beam scanning in the circumferential direction, or with the requirements of ASTM E 213-79. The reference standard shall be in accordance with NC-2552.3 below.

(c) *Acceptance Standard.* Products with defects that produce indications in excess of the indications produced by the standard defects in the reference specimen are unacceptable unless the defects are eliminated or repaired in accordance with NC-2558 or NC-2559.

NC-2552.2 Examination Procedure for Welds in Fittings

(a) *Procedure.* The procedure for ultrasonic examination of welds in fittings shall be in accordance with the requirements of Recommended Practice SA-388 for angle beam examination in two circumferential directions.

(b) *Acceptance Standard.* Fittings shall be unacceptable if angle beam examination results show one or more reflectors which produce indications exceeding in amplitude the indications from the calibrated notch.

NC-2552.3 Reference Specimens

(a) The reference specimen shall be of the same nominal diameter and thickness and of the same nominal composition and heat treated condition as the product which is being examined. For circumferential scanning, the standard defects shall be axial notches or grooves on the outside and inside surfaces of the reference specimen and shall have a length of approximately 1 in. (25 mm) or less, a width not to exceed $\frac{1}{16}$ in. (1.6 mm) for a square notch or U-notch, a width proportional to the depth for a V-notch, and a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the nominal wall thickness.

(b) The reference specimen shall be long enough to simulate the handling of the product being examined through the examination equipment. When more than one standard defect is placed in a reference specimen, the defects shall be located so that indications from each defect are separate and distinct without mutual interference or amplification. All upset metal and burrs adjacent to the reference notches shall be removed.

NC-2552.4 Checking and Calibration of Equipment.

The proper functioning of the examination equipment shall be checked, and the equipment shall be calibrated by the use of the reference specimens, as a minimum:

- (a) at the beginning of each production run of a given size and thickness of a given material;
- (b) after each 4 hr or less during the production run;
- (c) at the end of the production run;
- (d) at any time that malfunctioning is suspected.

If, during any check, it is determined that the testing equipment is not functioning properly, all of the product that has been tested since the last valid equipment calibration shall be reexamined.

NC-2553 Radiographic Examination

(a) *General.* When radiographic examination is performed as an alternative to ultrasonic examination of the entire volume of the material, it shall apply to the entire volume of the pipe, tube, or fitting material. Acceptance standards specified for welds shall apply to the entire volume of material examined.

(b) *Examination Procedure.* The radiographic examination shall be performed in accordance with Article 2 of Section V, as modified by NC-5111.

(c) *Acceptance Standard.* Welds that are shown by radiography to have any of the following types of discontinuities are unacceptable:

- (1) any type of crack or zone of incomplete fusion or penetration;
- (2) any other elongated indication which has a length greater than:
 - (a) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (b) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive
 - (c) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the thinner portion of the weld;

- (3) any group of aligned indications having an aggregate length greater than t in a length of $12t$, unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(4) rounded indications in excess of that shown as acceptable in Appendix VI.

NC-2554 Eddy Current Examination

This examination method is restricted to materials with uniform magnetic properties and of sizes for which meaningful results can be obtained.

NC-2554.1 Examination Procedure.

The procedure for eddy current examination shall provide a sensitivity that will consistently detect defects by comparison with the standard defects included in the reference specimen specified in NC-2552.3. Products with defects that produce indications in excess of the reference standards are unacceptable unless the defects are eliminated or repaired in accordance with NC-2558 or NC-2559 as applicable.

NC-2554.2 Reference Specimens.

The reference specimen shall be of the same nominal diameter and thickness and of the same nominal composition and heat treated condition as the product that is being examined. The standard shall contain tangential or circumferential notches on the outside surface plus a $\frac{1}{16}$ in. (1.6 mm) diameter hole drilled through the wall. These shall be used to establish the rejection level for the product to be tested. The reference notches shall have a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the wall thickness. The width of the notch shall not exceed $\frac{1}{16}$ in. (1.6 mm). The length shall be approximately 1 in. (25 mm) or less. The size of reference specimens shall be as specified in NC-2552.3.

NC-2554.3 Checking and Calibration of Equipment.

The checking and calibration of examination equipment shall be the same as in NC-2552.4.

Page 33

NC-2557 Time of Examination

(a) Products that are quenched and tempered shall be examined, as required, after the quenching and tempering heat treatment.

(b) Products that are not quenched and tempered shall receive the required examinations as follows:

(1) ultrasonic or eddy current examination, when required, shall be performed after final heat treatment, except postweld heat treatment;

(2) radiographic examination, when required, may be performed prior to any required postweld heat treatment;

(3) magnetic particle or liquid penetrant examination of welds, including repair welds, shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment for P-No. 1 (Section IX of the Code) materials of 2 in. (51 mm) and less nominal thickness;

(4) forgings and rolled bars which are to be bored and/or turned to form tubular parts or fittings shall be examined after boring and/or turning, except for threading; fittings shall be examined after final forming;

(5) when surface examination is required, all external surfaces and all accessible internal surfaces shall be examined, except for bolt holes and threads.

NC-2558 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is examined by the method which originally disclosed the defect to assure that the defect has been removed or reduced to an imperfection of acceptable size;

(c) if the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of

NC-3000, the product shall be repaired in accordance with NC-2559.

NC-2559 Repair by Welding

Repair of defects shall be in accordance with NC-2539, except repair by welding is not permitted on copper alloy and nickel alloy heat exchanger tubes.

NC-2560 EXAMINATION AND REPAIR OF TUBULAR PRODUCTS AND FITTINGS WELDED WITH FILLER METAL

NC-2561 Required Examination

(a) Welded (with filler metal) tubular products, such as pipe made in accordance with SA-358, SA-409, SA-671, SA-672, and SA-691 and fittings made in accordance with the WPW grades of SA-234, SA-403, and SA-420, which are made by welding with filler metal, shall be treated as material; however, inspection by an Inspector and stamping with an NPT symbol shall be in accordance with Section III requirements. In addition to the NPT symbol, a numeral 2 shall be stamped below and outside the official Code symbol.

(b) In addition to the requirements of the material specification and of this Article, all welds shall be examined 100% by radiography in accordance with the basic material specification. When radiographic examination is not specified in the basic material specification, the welds shall be examined in accordance with NC-2563.

(c) Tubular products and fittings which have been radiographed shall be marked to indicate that radiography has been performed. The radiographic film and a radiographic report showing film locations shall be provided with the Certified Material Test Report.

(d) The Authorized Inspector shall certify by signing the Partial Data Report Form NM-1 in accordance with NCA-5290.

NC-2563 Radiographic Examination

The radiographic examination shall be performed in accordance with the requirements of NC-2553.

NC-2567 Time of Examination

The time of examination shall be in accordance with the requirements of NC-2557.

NC-2568 Elimination of Surface Defects

Unacceptable surface defects shall be removed in accordance with the requirements of NC-2558.

NC-2569 Repair by Welding

When permitted by the basic material specification, base material defects shall be repair welded in accordance to the requirements of NC-2559. Repair welding

Page 34

of weld seam defects shall be in accordance with NC-4450.

NC-2570 EXAMINATION AND REPAIR OF STATICALLY AND CENTRIFUGALLY CAST PRODUCTS

In addition to the requirements of the material specification and of this Article NC-2000, statically and centrifugally cast products shall comply with the following paragraphs.

NC-2571 Required Examination

(a) Cast products shall be examined by volumetric and/or surface methods, including repairs, as required for the product form by Table NC-2571-1 Class 2 castings.

(b)

pressure ratings of Table NC-2571-2 shall be applied so as to reduce the required examinations of that Standard. The required examinations by ASME B16.34 for Special Class category valves shall be performed in accordance with the procedures and acceptance standards of this Subsection.

NC-2572 Time of Nondestructive Examination

NC-2572.1 Acceptance Examinations.

Acceptance examinations shall be performed at the time of manufacture as stipulated in the following and Table NC-2571-1.

(a) *Ultrasonic Examination.* Ultrasonic examination, if required, shall be performed at the same stage of manufacture as required for radiography.

(b) *Radiographic Examination.* Radiography may be performed prior to heat treatment and may be performed prior to or after finish machining at the following limiting thicknesses.

(1) For finished thicknesses under $2\frac{1}{2}$ in. (64 mm), castings shall be radiographed within 20% of the finished thickness when Type 2 radiographic film is used or within $\frac{1}{2}$ in. (13 mm) of the finished thickness when Type 1 radiographic film is used. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(2) For finished thickness from $2\frac{1}{2}$ in. (64 mm) up to 6 in. (152 mm), castings shall be radiographed within 20% of the finished thickness. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(3) For finished thicknesses over 6 in. (152 mm), castings shall be radiographed with $\frac{1}{2}$ in. (13 mm) or 15% of the finished thickness, whichever is greater. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(c) Radiography of castings for pumps and valves may be performed in as-cast or rough machined thickness exceeding the limits of NC-2572.1(b)(1), (b)(2), or (b)(3) subject to the following conditions.

(1) When the thickness of the as-cast or rough machined section exceeds 2 in. (51 mm) acceptance shall be based on reference radiographs for the next lesser thickness; e.g., if the section being radiographed exceeds $4\frac{1}{2}$ in. (114 mm), use reference radiographs of ASTM E 186-75 (reapproved 1979). The penetrometer shall be based on the thickness of the section being radiographed.

(2) When the thickness of the as-cast or rough machined section is 2 in. (51 mm) or less, the reference radiographs of ASTM E 446-78 shall be used, and the penetrometer shall be based on the final section thickness.

(3) Weld ends for a minimum distance of t or $\frac{1}{2}$ in. (13 mm), whichever is less (where t is the design section thickness of the weld), from the final welding end shall be radiographed at a thickness within the limits given in NC-2572.1 (b)(1), (b)(2), or (b)(3) as applicable. As an alternative, the weld ends may be radiographed in the as-cast or rough machined thickness in accordance with (c)(1) and (c)(2) above, and the penetrometer shall be based on the final section thickness.

(d) *Magnetic Particle or Liquid Penetrant Examination.* Magnetic particle or liquid penetrant examination shall be performed after the final heat treatment required by the material specification. Repair weld areas shall be examined after postweld heat treatment when a postweld heat treatment is performed, except that repair welds in P-No. 1 (see Section IX of the Code) material 2 in. (51 mm) nominal thickness and less may be examined prior to postweld heat treatment. For cast products with machined surfaces, all finished machine surfaces, except threaded surfaces and small deep holes, shall also be examined by magnetic particle or liquid penetrant methods.

NC-2573 Provisions for Repair of Base Material by Welding

The Material Manufacturer may repair, by welding, products from which defects have been removed, provided the requirements of this Article are met.

**TABLE NC-2571-1
REQUIRED EXAMINATIONS**

Nominal Pipe Size	Item	Applicable Special Requirements for Class 2 Castings
Inlet piping connections of 2 in. and less	Cast pipe fittings, pumps, and valves	None, except for ASME B16.34 Special Class category valves which shall be in accordance with NC-2571(b).
	Cast pressure retaining material other than pipe fittings, pumps, and valves	Cast pressure retaining materials shall be examined by either radiographic or ultrasonic methods, or a combination of the two methods. Castings or sections of castings, which have coarse grains or configurations which do not yield meaningful results by ultrasonic examination, shall be examined by radiographic methods (NC-2575).
	Repair welds in pumps and valves of P-No. 1 or P-No. 8 material	None
	Repair welds in cast pressure retaining material other than pumps and valves of P-No. 1 or P-No. 8 material	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, when radiography of the casting is required, repair welds in cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. or 10% of the section thickness, shall be radiographed in accordance with NC-2575.
Inlet piping connections over 2 in. up to and including 4 in.	Cast pumps and valves with a quality factor of 1.00	Magnetic particle or liquid penetrant examination may be performed on all external surfaces and on all accessible internal surfaces, in lieu of volumetric examination, except the weld ends of cast pumps and valves shall be radiographed for a minimum distance of t (where t is the design section thickness of the weld) from the final weld end. For ASME B16.34 Special Class category valves, see NC-2571(b).
	Cast pumps and valves with a quality factor of 0.70	None
	Cast pressure retaining material other than cast pumps and valves	Cast pressure retaining materials shall be examined by either radiographic or ultrasonic methods, or a combination of the two methods. Castings or sections of castings, which have coarse grains or configurations which do not yield meaningful results by ultrasonic examination, shall be examined by radiographic methods.
	Repair welds in pumps and valves of P-No. 1 or P-No. 8 material with a quality factor of 0.70	None
	Repair welds in cast pressure retaining material other than pumps and valves of P-No. 1 or P-No. 8 material with a quality factor of 0.70	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, when radiography of the casting is required, repair welds in cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. or 10% of the section thickness, shall be radiographed in accordance with NC-2474.
Inlet piping connections over 4 in.	Cast pressure retaining materials	Cast pressure retaining materials shall be examined by either radiographic or ultrasonic methods, or a combination of the two methods. Castings or sections of castings, which have coarse grains or configurations which do not yield meaningful results by ultrasonic examination, shall be examined by radiographic methods. For ASME B16.34 Special Class category valves, see NC-2571(b).
	Repair welds	Each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. In addition, when radiography of the casting is required, repair welds in cavities, the depth of which exceeds the less of $\frac{3}{8}$ in. or 10% of the section thickness, shall be radiographed in accordance with NC-2575.

TABLE NC-2571-1 REQUIRED EXAMINATIONS

NC-2573.1 Defect Removal.

The defects shall be removed or reduced to an imperfection of acceptable size by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair. When thermal cutting is performed, consideration shall be given to preheating the material.

NC-2573.2 Repair by Welding.

The Material Manufacturer may repair castings by welding after removing the material containing unacceptable defects. The depth of the repair is not limited. A cored hole or access hole may be closed by the Material Manufacturer by welding in accordance with the requirements of this subparagraph, provided the hole is closed by filler metal only. If the hole is closed by welding in a metal insert, the welding shall be performed by a holder of a Certificate of Authorization in accordance with the requirements of the Code.

NC-2573.3 Qualification of Welding Procedures and Welders.

Each manufacturer is responsible for the welding done by his organization and shall establish the procedures and conduct the tests required by NC-4000 and by Section IX of the Code in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures. He is also responsible for the welding performed by his subcontractors and shall assure himself that the subcontractors conduct the tests required by NC-4000 and by Section IX of the Code in order to qualify their welding procedures and the performance of their welders and welding operators.

NC-2573.4 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NC-2573.5 Examination of Repair Welds

(a) Each repair weld shall be examined by the magnetic particle method in accordance with the requirements of NC-2577, or by the liquid penetrant method in accordance with the requirements of NC-2576. In addition, when radiography is specified in the order for the original casting, repair cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the nominal wall thickness, shall be radiographed after repair except that weld slag, including elongated slag, shall be considered as inclusions under Category B of the applicable reference radiographs. The total area of all inclusions, including slag inclusions, shall not exceed the limits of the applicable severity level of Category B of the reference radiographs. The penetrameter and the acceptance standards for radiographic examination of repair welds shall be based on the actual section thickness at the repair area.

(b) Examination of repair welds in P-No. 1 and P-No. 8 materials is not required for pumps and valves with inlet piping connections 2 NPS and less.

NC-2573.6 Heat Treatment After Repairs.

The material shall be heat treated after repair in accordance with the heat treatment requirements of NC-4620, except that the heating and cooling rate limitations of NC-4623 do not apply.

NC-2573.7 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is reexamined by the magnetic particle method in accordance with NC-2577, or the liquid penetrant method in accordance with NC-2576, to assure that the defect has been removed or reduced to an imperfection of acceptable size;

(c) if the elimination of the defect reduces the section thickness below the minimum required by the specification or drawing, the casting shall be repaired in accordance with NC-2539.

NC-2573.8 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the nominal wall thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart that shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film, when radiographic film is specified in the order for the original casting.

NC-2574 Ultrasonic Examination of Ferritic Steel Castings

Ultrasonic examination shall be performed in accordance with T-541.4 of Article 5 of Section V. Each manufacturer shall certify that the procedure is in accordance with the requirements of NC-2574 and shall make the procedure available for approval upon request.

NC-2574.1 Acceptance Standards

(a) The Quality Levels of SA-609 as shown in Section V shall apply for the casting thicknesses indicated:

(1) Quality Level 1 for thicknesses up to 2 in. (51 mm);

Page 37

(2) Quality Level 3 for thicknesses 2 to 4 in. (51 mm to 102 mm);

(3) Quality Level 4 for thicknesses greater than 4 in. (152 mm).

(b) In addition to the Quality Level requirements stated in (a) above, the requirements in (1) through (5) below shall apply for both straight beam and angle beam examination.

(1) Areas giving indications exceeding the Amplitude Reference Line with any dimension longer than those specified in the following tabulation are unacceptable.

UT Quality Level

	Longest Dimension of Area¹¹¹²¹³
1	1.5 in.
2	2.0 in.
3	2.5 in.
4	3.0 in.

(2) Quality Level 1 shall apply for the volume of castings within 1 in. of the surface regardless of the overall thickness.

(3) Discontinuities indicated to have a change in depth equal to or greater than $\frac{1}{2}$ the wall thickness or 1 in. (25 mm) (whichever is less) are unacceptable.

(4) Two or more imperfections producing indications in the same plane with amplitudes exceeding the Amplitude Reference Line and separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable if they cannot be encompassed within an area less than that of the quality level specified in (1) above.

11 The areas for the Ultrasonic Quality Levels in SA-609 refer to the surface area on the casting over which a continuous indication exceeding the transfer corrected distance amplitude curve is maintained.

12 Areas are to be measured from dimensions of the movement of the search unit, using the center of the search unit as the reference point.

13 In certain castings, because of very long metal path distances or curvature of the examination surfaces, the surface area over which a given discontinuity is detected may be considerably larger or smaller than the actual area of the discontinuity in the casting. In such cases, other criteria which incorporate a consideration of beam angles or beam spread must be used for realistic evaluation of the discontinuity.

(5) Two or more imperfections producing indications greater than permitted for Quality Level 1 for castings less than 2 in. (51 mm) in thickness, greater than permitted for Quality Level 2 for thicknesses 2 in. (51 mm) through 4 in. (102 mm), and greater than permitted for Level 3 for thicknesses greater than 4 in. (102 mm), separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable, if they cannot be encompassed in an area less than that of the Quality Level requirements stated in (a) above.

NC-2575 Radiographic Examination

NC-2575.1 Examination.

Cast pressure retaining materials shall be examined by radiographic methods when specified in the order for the original castings, except that cast ferritic steels may be examined by either radiographic or ultrasonic methods, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by ultrasonic methods shall be examined by radiographic methods.

NC-2575.2 Extent.

Radiographic examination shall be performed on pressure retaining castings such as vessel heads and flanges, valve bodies, bonnets and disks, pump casings and covers, and piping and fittings. The extent of radiographic coverage shall be of the maximum feasible volume and, when the shape of the casting precludes complete coverage, the coverage shall be at least as exemplified in the typical sketches as shown in Fig. NC-2575.2-1.

NC-2575.3 Examination Procedure.

The radiographic examination shall be performed in accordance with Article 2 of Section V, with the following modifications.

(a) *Film Selection.* Only Types 1, 2, and 3 are permitted.

(b) *Radiographic Density.* The transmitted film density through the radiographic image of the body of the appropriate penetrometer, and the area of interest shall be 1.3 minimum for single film viewing. For composition viewing of multiple film exposures, each film of the composite set shall have a minimum density of 1.0. The maximum density shall be 4.0 for either single or composite viewing. A tolerance of 0.05 in density is allowed for variations between densitometer readings.

(c) The requirements of T-274 and T-285 of Article 2 of Section V need not be met.

(d) *Image Quality Indicator (IQI) Design.* Penetrators shall be manufactured and identified in accordance with the requirements or alternates allowed in SE-142 and Appendices.

(e) *Image Quality Indicator (IQI) Selection.* The radiographic quality level shall be 2-4T for section thicknesses up to and including $\frac{3}{4}$ in. (19 mm), and 2-2T for section thicknesses greater than $\frac{3}{4}$ in. (19 mm). Radiographic quality is defined in Note 2 of SE-94.

(f) When radiographing weld ends of cast valves NPS 4 and less, double wall radiography may be used subject to the conditions of (1) and (2) below.

Page 38

Page 40

Pages 39-39

(a) Typical Volute-Type Pump Case

GENERAL NOTES:

- (a) Radiographic examination areas shall be indicated by a circle at each change of direction. The examination symbol for radiography shall be indicated as RT.
- (b) For nondestructive examination areas of revolution, the area shall be indicated by the examine-all-around symbol: — RT — ⌀
- (c) The sketches are typical and are to be used as a guide for minimum required coverage. Even though a sketch may be titled, "pump" or "valve," the coverage shown by the configurations may be applied interchangeably.

(g) Typical Globe Valve

FIG. NC-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

FIG. NC-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

(1) The penetrameter thickness shall be based on the design section thickness of the double wall, excluding the weld preparation lip.

(2) Acceptance standards shall be based on nominal single wall thickness.

NC-2575.4 Procedure Requirements.

Radiographic examination shall be performed in accordance with a written procedure. Each manufacturer shall certify that the procedure is in accordance with the requirements of NB-2575. The procedure shall be available for the interpretation of the films and shall be submitted together with the radiographs. Each procedure shall include at least the following information:

(a) the type of material to be radiographed;

(b) the material thickness ranges to be radiographed;

(c) the type of radiation source, actual or maximum source size or focal spot, X-ray equipment voltage rating and manufacturer. The equipment manufacturer's or supplier's publications, such as technical manuals, decay curves, or written statements documenting the actual or maximum source size or focal spot, shall be acceptable as source size verification; for X-ray machines 320 KV and less, the focal spot size may be determined by the pinhole method;¹⁴

(d) type and thickness of intensifying screens and filters;

(e) minimum source-to-film distance.

NC-2575.5 Radiographic Setup Information.

To aid in proper interpretation of radiographs, details of the radiographic examination setup used shall accompany each group of radiographs. As a minimum, the information shall include:

(a) film brand and the type and number of films in the cassette;

(b) for multiple film technique, a statement whether viewing is to be single or superimposed;

(c) blocking or masking technique, if used;

(d) isotope or X-ray voltage used;

(e) source to film distance used;

(f) distance between film and object when film/cassette is not in contact with object;

(g) geometric arrangement for the radiograph(s) (sketch);

(h) orientation of location markers;

(i) description of how internal markers, when used, locate area of interest;

14 Nondestructive Testing Handbook, Volume I, First Edition, pp. 14.32-14.33, "Measuring Focal-Spot Size." Also, pp. 20-21 of "Radiography in Modern Industry," Fourth Edition.

(j) location markers, such as lead numbers or letters, which shall appear as radiographic images on the film, shall be permanently stamped on the surface of the casting being radiographed in a manner permitting the area of interest on a radiograph to be accurately located on the casting and providing evidence on the radiograph that the extent of coverage required by NC-2575.2 has been obtained. On castings or sections of castings where stamping is not feasible, the radiographic procedure shall so state, in which case a radiographic film location map shall be provided.

NC-2575.6 Acceptance Criteria.

Castings shall meet the acceptance requirements of Severity Level 2 of ASTM E 446-72, E 446-75 or E 446-78, Reference Radiographs for Steel Castings up to 2 in. in Thickness, ASTM E 186-67, ASTM E 186-73, or E 186-75,

Reference Radiographs for Heavy-Walled [2 to 4 1/2 in. (51 to 114 mm)] Steel Castings, or ASTM E 280-68, ASTM E 280-72, or ASTM E 280-75, Reference Radiographs for Heavy Walled [4 1/2 to 12 in. (114 mm to 305 mm)] Steel Castings, as applicable for the thickness being radiographed, except Category D, E, F, or G defects are not acceptable. The requirements of ASTM 280-68, ASTM E 280-72, or ASTM E 280-75 shall apply for castings over 12 in. in thickness.

NC-2576 Liquid Penetrant Examination

(a) Castings shall be examined, if required, on all accessible surfaces by liquid penetrant method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by bleeding out of the penetrant; however, localized surface discontinuities, as may occur from machining marks, scale, or dents, may produce indications which are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation that would mask indications of defects are unacceptable. Relevant indications are those which result from imperfections and have a major dimension greater than 1/16 in. Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than 1/16 in. (1.6 mm) long for materials less than 5/8 in. (16 mm) thick, greater than 1/8 in. (3.2 mm) long for materials from

Page 41

5/8 in. (16 mm) thick to under 2 in. (51 mm) thick, and 3/16 in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than 1/8 in. (3.2 mm) for thicknesses less than 5/8 in. (16 mm), and greater than 3/16 in. (4.8 mm) for thicknesses 5/8 in. (16 mm) and greater;

(3) four or more indications in a line separated by 1/16 in. or less edge to edge;

(4) ten or more indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NC-2577 Magnetic Particle Examination (for Ferritic Steel Products Only)

(a) Castings of magnetic material shall be examined, if required, on all accessible surfaces by a magnetic particle method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by retention of the examination medium. All indications are not necessarily defects since certain metallurgical discontinuities and magnetic permeability variations may produce indications that are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Nonrelevant indications which would mask indications of defects are unacceptable. Surface conditioning may precede the reexamination. Relevant indications are those which result from imperfections and have a major dimension greater than 1/16 in. (1.6 mm). Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than 1/16 in. (1.6 mm) long for materials less than 5/8 in. (16 mm) thick; greater than 1/8 in. (3.2 mm) long for materials from 5/8 in. (16 mm) thick to under 2 in. (51 mm) thick; and 3/16 in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than 1/8 in. (3.2 mm) for thicknesses less than 5/8 in. (16 mm), and

greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NC-2580 EXAMINATION OF BOLTS, STUDS, AND NUTS

NC-2581 Requirements

All bolting material shall be visually examined in accordance with NC-2582.

NC-2582 Visual Examination

Visual examination shall be applied to the areas of threads, shanks, and heads of final machined parts. Harmful discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

[98]

NC-2600 MATERIAL ORGANIZATIONS' QUALITY SYSTEM PROGRAMS

[98]

NC-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 shall be met as required by NC-2130. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, for brazing material, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Assurance Program (NCA-4000) shall include measures to provide assurance that the material is furnished in accordance with the material specification and with the applicable requirements of this Subsection.

Page 42

(c) For the purpose of this paragraph, small products are defined as given in (1) through (4) below:

(1) pipe, tube (except heat exchanger tube), pipe fittings, and flanges 2 in. nominal pipe size (DN 50) and less;

(2) bolting materials, including studs, nuts, and bolts of 1 in. (25 mm) nominal diameter and less;

(3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;

(4) material for pumps and valves with inlet pipe connections of 2 in. nominal pipe size (DN 50) and less;

(5) materials exempted by NC-2121(c).

[98]

NC-2700 DIMENSIONAL STANDARDS

Dimensions of standard items shall comply with the standards and specifications of Table NC-3132-1

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NC-3000

ARTICLE NC-3000 DESIGN

NC-3100 GENERAL DESIGN

NC-3110 LOADING CRITERIA

NC-3111 Loading Conditions

The loadings that shall be taken into account in designing a component shall include, but are not limited to, those in (a) through (g) below:

- (a) impact forces caused by either external or internal conditions;
- (b) impact loads, including rapidly fluctuating pressures;
- (c) weight of the component and normal contents under operating or test conditions, including additional pressure due to static and dynamic head of liquids;
- (d) superimposed loads such as other components, operating equipment, insulation, corrosion resistant or erosion resistant linings, and piping;
- (e) wind loads, snow loads, vibrations, and earthquake loads, where specified;
- (f) reactions of supporting lugs, rings, saddles, or other types of supports;
- (g) temperature effects.

NC-3112 Design Loadings

The Design Loadings shall be established in accordance with NCA-2142.1 and the following subparagraphs.

NC-3112.1 Design Pressure.

The specified internal and external Design Pressures to be used in this Subsection shall be established in accordance with NCA-2142.1(a).

NC-3112.2 Design Temperature.

The specified Design Temperature shall be established in accordance with NCA-2142.1(b). It shall be used in conjunction with the Design Pressure. If necessary, the metal temperature shall be determined by computation using accepted heat transfer procedures or by measurement from equipment in service under equivalent operating conditions. In no case shall the temperature at the surface of the metal exceed the maximum temperature listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, nor exceed the maximum temperature limitations specified elsewhere in this Subsection.

NC-3112.3 Design Mechanical Loads.

The specified Design Mechanical Loads shall be established in accordance with NCA-2142.1(c). They shall be used in conjunction with the Design Pressure.

NC-3112.4 Design Allowable Stress Values

(a) Allowable stresses for design for materials are listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, except for vessels designed to the requirements of NC-3200, for which the design stress intensity values are listed in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1. The materials shall not be used at metal and design temperatures above those for which stress or stress intensity values are given. The values in the Tables may be interpolated for intermediate temperatures.

(b) The maximum allowable compressive stress to be used in the design of cylindrical shells subjected to loadings that produce longitudinal compressive stress in the shell shall be the smaller of the following values:

(1) the maximum allowable tensile stress value permitted in (a) above;

(2) the value of the factor B determined from NC-3133.6(b).

It is recognized that high localized and secondary stresses may exist in components designed and fabricated in accordance with the rules of this Subsection; however, insofar as practical, design rules for details have been written to hold such stresses at a safe level consistent with experience.

(c) The wall thickness of a component computed by the rules of this Subsection shall be determined so that the general membrane stress due to any combination of mechanical loadings listed in NC-3111 which are expected to occur simultaneously during a condition of loading for which service Level A is designated for the component does not exceed¹ the maximum allowable stress value permitted at the Design Temperature unless

Page 58

specifically permitted in other paragraphs of this Subsection. These allowable stress values may be interpolated for intermediate Design Temperature.

NC-3113 Service Conditions

(a) Each service condition to which the components may be subjected shall be classified in accordance with NCA-2142, and Service Limits [NCA-2142.4(b)] shall be designated in the Design Specifications in such detail as will provide a complete basis for design in accordance with this Article.

(b) When any loadings for which Level B, C, or D Service Limits are designated are specified in the Design Specifications, they shall be evaluated in accordance with NCA-2140 and in compliance with the applicable design and stress limits of this Article.

NC-3120 SPECIAL CONSIDERATIONS

NC-3121 Corrosion

Materials subject to thinning by corrosion, erosion, mechanical abrasion, or other environmental effects shall have provision made in the Design Specifications for these effects by indicating the increase in the thickness of the base metal over that determined by the design formulas (NC-2160). Other suitable methods of protection may be used. Material added or included for these purposes need not be of the same thickness for all areas of the component if different rates of attack are expected for the various areas.

NC-3122 Cladding

The rules of this paragraph apply to the design of clad components constructed of material permitted in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

NC-3122.1 Stresses.

Except as permitted by NC-3214, no structural strength shall be attributed to the cladding.

NC-3122.2 Design Dimensions.

The dimensions given in (a) and (b) below shall be used in the design of the component:

(a) for components subjected to internal pressure, the inside diameter shall be taken at the nominal inner face of the cladding;

(b) for components subjected to external pressure, the outside diameter shall be taken at the outer face of the base metal.

NC-3123 Welds Between Dissimilar Metals

In satisfying the requirements of this Subarticle, caution shall be exercised in construction involving dissimilar metals having different chemical compositions, mechanical properties, and coefficients of thermal expansion in order to avoid difficulties in service.

difficulties in service.

NC-3124 Ductile Behavior Evaluation

The use of material below the temperature established by the methods of NC-2331(a) may be justified by methods equivalent to those contained in Appendix G.

NC-3125 Configuration

Accessibility to permit the examinations required by the Edition and Addenda of Section XI as specified in the Design Specification for the component shall be provided in the design of the component.

NC-3130 GENERAL DESIGN RULES

NC-3131 General Requirements

The design shall be such that the rules of this Article are satisfied for all configurations and loadings, using the maximum allowable stress values S of Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 in the various equations and including the use of the standard products listed in Table NC-3132-1. Use of the maximum allowable stress values of Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 does not apply to vessels designed to the rules of NC-3200.

NC-3131.1 Design Reports

(a) The N Certificate Holder is required to provide a Design Report as part of the responsibility for achieving structural integrity of the component. The Design Report shall be certified when required by NCA-3550.

(b) The Certificate Holder for construction of a vessel conforming to the design requirements of NC-3200 shall provide a Design Report conforming to the requirements of NC-3211 and NC-3223.2.

NC-3131.2 Proof Test to Establish Maximum Design Pressure.

When the configuration of a component is such that the stresses resulting from internal or external pressure cannot be determined with adequate accuracy by the rules of this Article, the maximum Design Pressure shall be determined by proof testing in accordance with the rules of NC-6900 except for piping as otherwise provided in this Article. This procedure

does not apply to vessels designed to the requirements of NC-3200.

NOTES:

- (1) Analysis per ANSI B16.9, paragraph 2.2, is acceptable only for caps and reducers.
(2) Analysis per ANSI B16.28, paragraph 2.2, is not acceptable.

TABLE NC-3132-1 DIMENSIONAL STANDARDS

NC-3132 Dimensional Standards for Standard Products

Dimensions of standard products shall comply with the standards and specifications listed in Table NB-3132-1 when the standard or specification is referenced in the specific design Subarticle. However, compliance with these standards does not replace or eliminate the requirements for stress analysis when called for by the design Subarticle for a specific component.

NC-3133 Components Under External Pressure

NC-3133.1 General.

Rules are given in this paragraph for determining the thickness under external pressure loading in spherical shells, cylindrical shells with or without stiffening rings, and tubular products consisting of pipes, tubes, and fittings. Charts for determining the stresses in shells and hemispherical heads are given in Section II, Part D, Subpart 3. For vessels

designed to NC-3200, see NC-3240.

NC-3133.2 Nomenclature.

The symbols used in this paragraph are defined as follows:

A	= factor determined from Fig. G, Section II, Part D, Subpart 3 in Section II, Part D, Subpart 3 and used to enter the applicable material chart in Section II, Part D, Subpart 3. For the case of cylinders having D_o/T values less than 10, see NC-3133.3(b).
B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a stiffening ring, corresponding to the factor B and the design metal temperature for the shell under consideration.
A_s	= cross-sectional area of a stiffening ring, sq in.
D_o	= outside diameter of the cylindrical shell course or tube under consideration, in.
E	= modulus of elasticity of material at Design Temperature, psi. For external pressure and axial compression design in accordance with this Section the modulus of elasticity to be used shall be taken from the applicable materials chart in Section II, Part D, Subpart 3. (Interpolation may be made between lines for intermediate temperatures.) The modulus of elasticity values shown in Section II, Part D, Subpart 3 for material groups may differ from those values listed in Tables TM, Section II, Part D, Subpart 2 for specific materials. Section II, Part D, Subpart 3 values shall be applied only to external pressure and axial compression design.
I	= available moment of inertia of the stiffening ring about its neutral axis, parallel to the axis of the shell, in. ⁴
I'	= available moment of inertia of the combined ring-shell cross section about its neutral axis, parallel to the shell, in. ⁴ The width of the shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10 \sqrt{D_o T_n}$ and shall be taken as lying one half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing to more than one stiffening ring.
I_s	= required moment of inertia of the stiffening ring about its neutral axis parallel to the axis of the shell, in.
I'_s	= required moment of inertia of the combined ring-shell section about its neutral axis parallel to the axis of the shell, in. ⁴
L	= total length of a tube between tubesheets, or the design length of a vessel section, taken as the largest of the following:

	(1) the distance between head tangent lines plus one-third of the depth of each head if there are no stiffening rings; (2) the greatest center-to-center distance between any two adjacent stiffening rings; or (3) the distance from the center of the first stiffening ring to the head tangent line plus one-third of the depth of the head, all measured parallel to the axis of the vessel, in.
L_s	= one-half of the distance from the center line of the stiffening ring to the next line of support on one side, plus one-half of the center line distance to the next line of support on the other side of the stiffening ring, both measured parallel to the axis of the component, in. A line of support is: (1) a stiffening ring that meets the requirements of this paragraph; (2) a circumferential line on a head at one-third the depth of the head from the head tangent line; or (3) a circumferential connection to a jacket for a jacketed section of a cylindrical shell.
P	= external Design Pressure, psi (gage or absolute, as required)
P_a	= allowable external pressure, psi (gage or absolute, as required)
R	= inside radius of spherical shell, in.
S	= the lesser of twice the allowable stress at design metal temperature from Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 or 0.9 times the tabulated yield strength at design metal temperature from Tables Y-1, Section II, Part D, Subpart 2, psi
T	= minimum required thickness of cylindrical shell or tube, or spherical shell, in.
T_n	= nominal thickness used, less corrosion allowance, of a cylindrical shell or tube, in.

NC-3133.3 Cylindrical Shells and Tubular Products.

The thickness of cylinders under external pressure shall be determined by the procedure given in (a) or (b) below.

(a) Cylinders having D_o/T values ≥ 10 :

Step 1: Assume a value for T and determine the ratios L/D_o and D_o/T .

Step 2: Enter Fig. G, Section II, Part D, Subpart 3 in Section II, Part D, Subpart 3 at the value of L/D_o determined in Step

1. For values of L/D_o greater than 50, enter the chart at a value of $L/D_o = 50$. For values of L/D_o

Page 61

less than 0.05, enter the chart at a value of L/D_o of 0.05.

Step 3: Move horizontally to the line for the value of D_o/T determined in Step 1. Interpolation may be made for immediate values of D_o/T . From this point of intersection move vertically downward to determine the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A

falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 7.

Step 5: From the intersection obtained in Step 4, move horizontally to the right and read the value of B .

Step 6: Using this value of B , calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{4B}{3(D_o/T)}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated using the following formula:

$$P_a = \frac{2AE}{3(D_o/T)}$$

Step 8: Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value of P_a is obtained that is equal to or greater than P .

(b) Cylinders having D_o/T values <10:

Step 1: Using the same procedure as given in (a) above, obtain the value of B . For values of D_o/T less than 4, the value of

factor A can be calculated using the following formula:

o

$$A = \frac{1.1}{(D_o / T)^2}$$

For values of A greater than 0.10, use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{a1} using the following formula:

$$P_{a1} = \left[\frac{2.167}{(D_o / T)} - 0.0833 \right] B$$

Step 3: Calculate a value P_{a2} using the following formula:

$$P_{a2} = \frac{2S}{D_o/T} \left[1 - \frac{1}{D_o/T} \right]$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2, or P_{a2} calculated in Step 3 shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NC-3133.4 Spherical Shells and Formed Heads

(a) *Spherical Shells*. The minimum required thickness of a spherical shell under external pressure, either seamless or of built-up construction with butt joints, shall be determined by the procedure given in Steps 1 through 6.

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 5.

Page 62

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B .

Step 4: Using the value of B obtained in Step 3, calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{B}{(R/T)}$$

Step 5: For values of A falling to the left of the applicable material/temperature line for the Design Temperature, the value of P_a can be calculated using the following formula:

$$P_a = \frac{0.0625E}{(R/T)^2}$$

Step 6: Compare P_a obtained in Steps 4 or 5 with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

(b) The nomenclature defined below is used in the formulas of (c) through (e) below.

D_o	= outside diameter of the head skirt or the outside diameter of a cone head at the point under consideration, measured perpendicular to the longitudinal axis of the cone, in.
K_1	= a factor depending on the ellipsoidal head proportions, given in Table NC-3332.2-1
R	= for hemispherical heads, the inside radius in the corroded condition, in.
R	= for ellipsoidal heads, the equivalent inside spherical radius taken as $K_1 D_o$ in the corroded condition, in.

R	= for torispherical heads, the inside radius of the crown portion of the head in the corroded condition, in.
T	= minimum required thickness of head after forming, exclusive of corrosion allowance, in.

(c) *Hemispherical Heads.* The required thickness of a hemispherical head having pressure on the convex side shall be determined in the same manner as outlined in (a) above for determining the thickness for a spherical shell.

(d) *Ellipsoidal Heads.* The required thickness of an ellipsoidal head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the following procedure.

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, follow the same procedure as that given for spherical shells in (a) above, Steps 2 through 6.

(e) *Torispherical Heads.* The required thickness of a torispherical head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the same design procedure as is used for ellipsoidal heads given in (d) above, using the appropriate value for R .

NC-3133.5 Stiffening Rings for Cylindrical Shells

(a) The required moment of inertia of a circumferential stiffening ring shall be not less than that determined by one of the following two formulas:

$$I_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{14}$$

$$I'_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{10.9}$$

If the stiffeners should be so located that the maximum permissible effective shell sections overlap on either or both sides of a stiffener, the effective shell section for that stiffener shall be shortened by one-half of each overlap.

(b) The available moment of inertia I or I' for a stiffening ring shall be determined by the following procedure.

Step 1: Assuming that the shell has been designed and D_o , L_s , and T_n are known, select a member to be used for the stiffening ring and determine its cross-sectional area A_s . Then calculate factor B using the following formula:

$$B = 3/4 \left[\frac{PD_o}{T_n + A_s / L_s} \right]$$

Step 2: Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined by Step 1. If different materials are used for the shell and stiffening

ring, use the material chart resulting in the larger value of A in Step 4 or 5, below.

Step 3: Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4: Move vertically to the bottom of the chart and read the value of A .

Step 5: For values of B falling below the left end of the material/temperature line for the design temperature, the value of A can be calculated using the formula

$$A = \frac{2B}{E}$$

Step 6: Compute the value of the required moment of inertia from the formulas for I_s or I'_s above.

Step 7: Calculate the available moment of inertia I or I' of the stiffening ring using the section corresponding to that used in Step 6.

Step 8: If the required moment of inertia is greater than the moment of inertia for the section selected in Step 1, a new section with a larger moment of inertia must be selected and a new moment of inertia determined. If the required moment of inertia is smaller than the moment of inertia for the section selected in Step 1, that section should be satisfactory.

(c) For fabrication and installation requirements for stiffening rings, see NC-4437.

NC-3133.6 Cylinders Under Axial Compression.

The maximum allowable compressive stress to be used in the design of cylindrical shells and tubular products subjected to loadings that produce longitudinal compressive stresses in the shell or wall shall be the lesser of the values given in (a) or (b) below:

(a) the S value for the applicable material at design temperature given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1;

(b) the value of the B determined from the applicable chart in Section II, Part D, Subpart 3 using the following definitions for the symbols on the charts:

T = minimum required thickness of the shell or tubular product, exclusive of the corrosion allowance, in.

R = inside radius of the cylindrical shell or tubular product, in.

The value of B shall be determined from the applicable chart contained in Section II, Part D, Subpart 3 as given in Steps 1 through 5.

Step 1: Using the selected values of T and R , calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 4.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B . This is the maximum allowable compressive stress for the values of T and R used in Step 1.

Step 4: For values of A falling to the left of the applicable material/temperature line, the value of B shall be calculated using the following formula:

$$B = \frac{AE}{2}$$

Step 5: Compare the value of B determined in Steps 3 or 4 with the computed longitudinal compressive stress in the cylindrical shell or tube, using the selected values of T and R . If the value of B is smaller than the computed

compressive stress, a greater value of T must be selected and the design procedure repeated until a value of B is obtained which is greater than the compressive stress computed for the loading on the cylindrical shell or tube.

NC-3133.7 Conical Heads.

The required thickness of a conical head under external pressure shall not be less than that determined by the rules of (a), (b), and (c) below.

Page 64

(a) When one-half of the included apex angle of the cone is equal to or less than $22\frac{1}{2}$ deg., the thickness of the cone shall be the same as the required thickness of a cylindrical shell, the length of which equals the axial length of the cone or the axial distance center to center of stiffening rings, if used, and the outside diameter of which is equal to the outside diameter at the large end of the cone or section between stiffening rings.

(b) When one-half of the included apex angle of the cone is greater than $22\frac{1}{2}$ deg. and not more than 60 deg., the thickness of the cone shall be the same as the required thickness of a cylindrical shell, the outside diameter of which equals the largest inside diameter of the cone measured perpendicularly to the cone axis, and the length of which equals an axial length that is the lesser of either the distance center to center of stiffening rings, if used, or the largest inside diameter of the section of the cone considered.

(c) When one-half of the included apex angle of the cone is greater than 60 deg., the thickness of the cone shall be the same as the required thickness for a flat head under external pressure, the diameter of which equals the largest inside diameter of the cone (NC-3325).

NC-3133.8 Tubes and Pipes When Used as Tubes.

The required wall thickness for tubes and pipes under external pressure shall be determined in accordance with Fig. NC-3133.8-1.

NC-3135 Attachments

(a) Except as in (c) and (d) below, attachments and connecting welds within the jurisdictional boundary of the component as defined in NC-1130 shall meet the stress limits of the component.

(b) The design of the component shall include consideration of the interaction effects and loads transmitted through the attachment to and from the pressure retaining portion of the component. For vessels designed to NC-3200, thermal stresses, stress concentrations, and restraint of the pressure retaining portion of the component shall be considered.

(c) Beyond $2t$ from the pressure retaining portion of the component, where t is the nominal thickness of the pressure retaining material, the appropriate design rules of NF-3000 may be used as a substitute for the design rules of NC-3000 for portions of attachments which are in the component support load path.

(d) Nonstructural attachments shall meet the requirements of NC-4435.

NC-3200 ALTERNATIVE DESIGN RULES FOR VESSELS

NC-3210 GENERAL REQUIREMENTS

NC-3211 Basis for Use

NC-3211.1 Scope

(a) This Subarticle contains design rules for vessels which may be used as an alternative to the design rules in NC-3300. When these requirements are met for design, the stress intensity values of 2A, 2B, and 4, Section II, Part D, Subpart 1 may be used.

(b) These requirements provide specific design rules for some commonly used vessel shapes under pressure loadings and, within specified limits, rules for treatment of other loadings. Simplified rules are also included for the approximate

evaluation of design cyclic service life. Rules are not given which cover all details of design.

(c) When complete rules are not provided or when the vessel designer chooses, a complete stress analysis of the vessel or vessel region shall be performed considering all the loadings of NC-3212 and the Design Specifications. This analysis shall be done in accordance with Appendix XIII for all applicable stress categories. Alternatively, an experimental stress analysis shall be performed in accordance with Appendix II.

(d) When these alternative design rules are used, the special requirements of NC-4260, NC-5250, NC-6221, and NC-6222 shall be met.

(e) A Design Report shall be prepared by the Certificate Holder showing compliance with this Subarticle. This Design Report shall meet the requirements of NCA-3550 for a Design Report (Appendix C).

NC-3211.2 Requirements for Acceptability

(a) The design shall be such that the requirements of NC-3100 and this Subarticle are satisfied. In cases of conflict, the requirements of this Subarticle shall govern.

(b) The design shall be such that stress intensities do not exceed the limits given in NC-3216.

(c) For configurations where compressive stresses occur, the critical buckling stress shall be taken into account. For the special case of external pressure, the rules of NC-3133 shall be met.

NC-3211.3 Materials in Combination

(a) A vessel may be designed for and constructed of any combination of materials permitted in 2A, 2B, and 4, Section II, Part D, Subpart 1, provided the applicable rules are followed and the requirements in Section IX for welding dissimilar metals are met.

Page 65

Page 66

FIG. NC-3133.8-1 CHART FOR DETERMINING WALL THICKNESS OF TUBES UNDER EXTERNAL PRESSURE

FIG. NC-3133.8-1 CHART FOR DETERMINING WALL THICKNESS OF TUBES UNDER EXTERNAL PRESSURE

(b) A stress analysis of a vessel region shall be made in accordance with Appendix XIII unless all of the provisions of (c) or (d) below apply. This does not obviate the need for such analysis where required by other provisions of this Subarticle.

(c)(1) The junction is a girth seam between pressure parts.

(2) Any taper required because of different thickness shall be in the material having the higher design stress intensity, or in weld deposit appropriate for the stronger material.

(3) No discontinuity is involved except that due to thickness and modulus of elasticity difference.

(4) $S_{m2} \leq 1.2 S_{m1}(E_2/E_1)$ where subscripts 1 and 2 denote the material having the lower and higher design stress intensity value, respectively, and S_m and E are as defined in NC-3216 and NC-3219, respectively.

(d)(1) The junction is at a seam between pressure parts other than a girth seam covered by (c) above.

(2) Any taper required because of different thickness is in material having the higher design stress intensity or in weld deposit appropriate for the stronger material.

(3) $S_{m2} \leq 1.1 S_{m1}(E_2/E_1)$ where subscripts and symbols are as given in (c)(4) above.

NC-3211.4 Combination Units.

When a vessel unit consists of more than one independent chamber, operating at the same or different pressures and temperatures, each chamber or vessel shall be designed and constructed to withstand the most severe condition of coincident pressure and temperature expected. Chambers which come within the scope of this Subarticle may be connected to chambers constructed to the rules of NC-3300, provided the connection between such chambers meets all of the requirements of this Subarticle.

NC-3211.5 Minimum Thickness of Shell or Head.

The thickness after forming and without allowance for corrosion of any shell or head subject to pressure shall be not less than $\frac{1}{4}$ in. (6 mm) for carbon and low alloy steels or $\frac{1}{8}$ in. (3.2 mm) for stainless steel.

NC-3211.6 Selection of Material Thickness.

The selected thickness of material shall be such that the forming, heat treatment, and other fabrication processes will not reduce the thickness of the material at any point below the minimum value required by these rules.

NC-3212 Loadings

The requirements of NC-3111 shall apply.

NC-3214 Cladding

The design calculations shall be based on a thickness equal to the nominal thickness of the base plate plus S_c/S_b times the nominal thickness of the cladding, less any allowance provided for corrosion, provided the conditions of (a), (b), and (c) below are met.

(a) The clad product conforms to one of the clad plate products referenced in NC-2121 or is overlay weld clad.

(b) The joints are completed by depositing corrosion resisting weld metal over the weld in the base material to restore the cladding.

(c) The S_m value of the weaker material is at least 70% of the S_m value of the stronger. Where

S_c

= design stress intensity value for the cladding or, for the weld overlay, that of the wrought material whose chemistry most closely approximates that of the cladding, at the Design Temperature, psi

S_b

= design stress intensity value for the base material at the Design Temperature, psi

the design stress intensity value shall be that given for base material in 2A, 2B, and 4, Section II, Part D, Subpart 1. When S_c is greater than S_b , the multiplier S_c/S_b shall be taken equal to unity.

NC-3215 Design Basis

NC-3215.1 Pressure and Temperature Relationships

(a) Table NC-3215.1(a)-1 sets forth the pressure, temperature, and static head relationships which shall be considered by the designer.

(b) The design for a vessel part is usually controlled by coincident pressure and temperature at a point. The design shall take into account the maximum difference in fluid pressure, which exists under the specified service conditions, between the inside and outside of the vessel at any point or between two chambers of a combination unit. The design thickness for pressure shall not include any metal added as corrosion or erosion allowance or any metal required for any combination of loadings listed in NC-3218 which are likely to occur coincident with the service pressure and temperature.

NC-3215.2 Definitions

(a) *Design Pressure.* The provisions of NC-3112.1 shall apply.

(b) *Design Temperature.* The provisions of NC-3112.2 shall apply.

(c) *Service Conditions.* The provisions of NC-3113 shall apply.

Page 67

Page 68

TABLE NC-3215.1(a)-1
PRESSURE AND TEMPERATURE RELATIONSHIPS

Condition	Pressure at Top of Vessel	Pressure Due to Static Head [Note (1)]	Temperature	Remarks
Condition 1 For vessel as a whole	Design Pressure	None	Coincident metal	Pressure and temperature to be stamped on nameplate
At any point	Coincident pressure	Pressure to point under consideration due to static head of vessel contents	Design coincident temperature	Temperature at various points may vary, in which case the maximum for these conditions shall be used for the vessel as a whole or coincident conditions for specific locations shall be listed on the Certificate Holder's Data Report and Stamping.
Condition 2 At any point	Coincident pressure	Coincident pressure to point under consideration due to static head	Design Temperature	Higher temperature and lower pressure combinations (than Condition 1) shall be checked or a part may be designed for the Maximum Design Pressure and the Design Temperature.
Condition 3 For vessel as a whole	Test pressure	None	Test temperature	
At any point	Test pressure	Pressure at point under consideration due to static head	Test Temperature	
Condition 4 For vessel as a whole or any part	Coincident pressure		Minimum permissible temperature	Minimum permissible temperature is used together with impact testing to determine suitability of material at service temperature.
	Safety valve setting			Usually set above the service pressure but not over the limits set in NC-7000

NOTE:

(1) Similar applications shall be made for other sources of pressure variation such as that resulting from flow.

TABLE NC-3215.1(a)-1 PRESSURE AND TEMPERATURE RELATIONSHIPS

(d) *Test Pressure.* The test pressure is the pressure to be applied at the top of the vessel during the test. This pressure plus any pressure due to static head at any point under consideration is used in the applicable formula to check the vessel under test conditions.

(e) *Safety Valve Setting.* The pressure for which the safety or safety relief valves are set to open is established by NC-7000.

NC-3216 Design Stress Intensity Values

NC-3216.1 Stress Tables.

The design stress intensity values S_m are given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1. Values for intermediate temperatures may be found by interpolation. These S_m values form the basis for the various stress limits which are described in Appendix XIII and are used in determining the membrane stress intensity limits for the various load combinations given in Table NC-3217-1.

NC-3216.2 Coefficients of Thermal Expansion and Moduli of Elasticity.

Values of the coefficients of thermal expansion are in Tables TE, Section II, Part D, Subpart 2 and values of the moduli of elasticity are in Tables TM, Section II, Part D, Subpart 2.

NC-3216.3 Special Stress Limits.

The deviations given in (a), (b), and (c) below from the basic stress limits are provided to cover special conditions or configurations.

(a) *Bearing Loads*

(1) The average bearing stress for resistance to crushing under the maximum design load shall be limited to the yield strength S_y at temperature except that, when the distance to a free edge is greater than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted. For clad surfaces, the yield strength of the base metal may be used if, when calculating the bearing stress, the bearing area is taken as the lesser of the actual contact area or the area of the base metal supporting the contact surface.

(2) When bearing loads are applied on parts having free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. The average shear stress shall be limited to $0.6S_m$ in the case of design load stress [XIII-1123(k)] and to $0.5S_y$ in the case of design load stress plus secondary stress [XIII-1123(h)]. For clad surfaces, if the configuration or thickness is such that a shear failure could occur entirely within the clad material, the allowable shear stress for the cladding shall be determined from the properties of the equivalent wrought material. If the configuration is such that a shear failure could occur across a path that is partially base metal and partially clad material, the allowable shear stresses for each material shall be used when evaluating the combined resistance to this type of failure.

(3) When considering bearing stresses in pins and similar members, the S_y value at temperature is applicable, except that a value of $1.5S_y$ may be used if no credit is given to bearing area within one pin diameter from a plate edge.

(b) *Pure Shear.* The average primary shear stress across a section under Design Loadings in pure shear, for example, keys, shear rings, and screw threads, shall be limited to $0.6S_m$. The maximum primary shear under Design Loadings, exclusive of stress concentration at the periphery of a solid circular section in torsion, shall be limited to $0.8S_m$.

(c) *Progressive Distortion of Nonintegral Connections.* Screwed-on caps, screwed-in plugs, shear ring closures, and breech lock closures are examples of nonintegral connections which are subject to failure by bell mouthing or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete operating cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can eventually lose engagement. Therefore, primary plus

secondary stress intensities (XIII-1145), which result in slippage between the parts of a nonintegral connection in which disengagement could occur as a result of progressive distortion, shall be limited to the value S_y given in Tables Y-1, Section II, Part D, Subpart 2.

NC-3217 Design Criteria

These design requirements provide specific design rules for certain commonly used pressure vessel shapes under pressure loading and, within prescribed limits, rules for the treatment of other loadings. Simplified criteria are included for determining whether an analysis for cyclic operation shall be made. The thickness of the vessel parts and attached supports covered by these rules shall be determined by the applicable formula using the most severe combination of loadings and design stress intensities kS_m expected to occur simultaneously during Design, Service, and Test. The basis for these formulas is given in (a) through (d) below. Table NC-3217-1 lists values of k that are appropriate for various load combinations.

(a) The theory of failure used in this Subarticle is the maximum shear stress theory, except in the case

Page 69

of some specifically designated configurations, shapes, or design rules included as a part of this Subarticle. Stress intensity is defined as two times the maximum shear stress.

**TABLE NC-3217-1
STRESS INTENSITY k FACTORS FOR DESIGN,
SERVICE, AND TEST LOAD COMBINATIONS**

Service Limits [Note (1)]	k [Note (2)]
Design	1.0
Level A [Note (3)]	1.0
Level B [Note (3)]	1.1
Level C	1.2
Level D [Note (4)]	2.0
Test	1.25 for hydrostatic test and 1.15 for pneumatic test (see NC-3218.1 for special limits)

NOTES:

- (1) For Design Limits, use Design Pressure at design metal temperature; for Service Limits, use service pressure at service metal temperature; for Test Limits, use test pressure at test metal temperature.
- (2) The condition of structural instability or buckling must be considered.
- (3) See NC-3219 and Appendix XIV.
- (4) When a complete analysis is performed in accordance with NC-3211.1(c), the stress limits of Appendix F may be applied.

TABLE NC-3217-1 STRESS INTENSITY k FACTORS FOR DESIGN, SERVICE AND TEST LOAD COMBINATIONS

(b) The average value of the general primary membrane stress intensity across the thickness of the section under consideration P_m , due to any combination of pressure and mechanical loadings expected to occur simultaneously, should not exceed the design stress intensity value kS_m .

(c) The local primary membrane stress intensity P_L due to any combination of pressure and mechanical loadings expected to occur simultaneously is limited to $1.5kS_m$. The distance over which the stress intensity exceeds $1.1kS_m$ shall not extend in the meridional direction more than $1.0\sqrt{Rt}$, where R is the mean radius at the midsurface of the shell or head and t is the nominal thickness of the shell or head at the point under consideration.

(d) The general or local primary membrane plus bending stress intensity (P_m or P_L) + P_b due to any combination of pressure and mechanical loadings expected to occur simultaneously shall not exceed $1.5kS_m$. When the design of vessels involves combinations of calculated stresses, the provisions of Appendix XIII apply.

NC-3217.1 Secondary Stresses.

Secondary stresses may exist in vessels designed and fabricated in accordance with the rules of this Subarticle, but limitations are provided to restrict such stresses to levels consistent with the rules in Appendix XIII. Where details are not covered or where design conditions exceed the formula limitations, a detailed stress analysis in accordance with the rules of Appendix XIII shall be made. Secondary stresses need be evaluated only for Level A and Level B Limits.

NC-3217.2 Definitions

P_m	= general primary membrane stress intensity, psi. This stress intensity is derived from the average value across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
P_L	= local primary membrane stress intensity, psi. This stress intensity is derived from the average value across the solid section under consideration. It considers discontinuities but not concentrations.
P_b	= primary bending stress intensity, psi. This stress intensity is the component of primary stress proportional to distance from centroid of solid section. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
S_m	= design stress intensity values given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1, psi
S_y	= yield strength values given in Tables Y-1, Section II, Part D, Subpart 2, psi

NC-3218 Upper Limits of Test Pressure

If the test pressure at any point in a vessel, including static head, exceeds the required test pressure defined in NC-6221 or NC-6231 by more than 6%, the upper limit shall be established by the designer using all the loadings that may exist during the test.

(a) *Hydrostatically Tested Vessels.* The hydrostatic test pressure of a completed vessel shall not exceed that value which results in the following stress intensity limits:

(1) a calculated primary membrane stress intensity P of 90% of the tabulated yield strength S at test temperature as

given in Tables Y-1, Section II, Part D, Subpart 2;

m

y

(2) a calculated primary membrane plus primary bending stress intensity $P_m + P_b$ shall not exceed the applicable limits given in (a) or (b) below:

$$(a) P_m + P_b \leq 1.35 S_y$$

$$\text{for } P_m \leq 0.67 S_y$$

$$(b) P_m + P_b \leq (2.15 S_y - 1.2 P_m) \\ \text{for } 0.67 S_y < P_m \leq 0.90 S_y$$

where S_y is the tabulated yield strength at test temperature.

(b) *Pneumatically Tested Vessels.* The limits given in (a) above shall apply to pneumatically tested vessels, except that the calculated membrane stress intensity shall be limited to 80% of the yield strength at the test temperature.

(c) *Multichamber Vessels.* In the case of multichamber vessels, pressure may be applied simultaneously to the appropriate adjacent chamber to maintain the stress intensity limits given in (a) and (b) above (NC-6600).

NC-3219 Fatigue Evaluation

When determining whether or not a fatigue analysis shall be specified, the Owner may consider experience with comparable vessels under similar conditions in accordance with the provisions of NC-3219.1. When not based upon significant applicable service experience, the need for a fatigue analysis shall be determined in accordance with the provisions of NC-3219.2 and NC-3219.3.

NC-3219.1 Service Experience.

When the Owner is considering experience with comparable vessels under similar service conditions as related to the design and service contemplated, particular attention shall be given to the possible deleterious effects of the design features of (a) through (e) below:

(a) nonintegral construction, such as the use of pad type reinforcements or of fillet welded attachments, as opposed to integral construction;

(b) use of pipe threaded connections, particularly for diameters in excess of $2\frac{3}{4}$ in. (70 mm);

(c) stud bolted attachments;

(d) partial penetration welds;

(e) major thickness changes between adjacent members.

NC-3219.2 Rules to Determine Need for Fatigue Analysis of Integral Parts of Vessels.

A fatigue analysis need not be made, provided *all* of Condition A or *all* of Condition B is met. If neither Condition A nor B is met, a detailed fatigue analysis shall be made in accordance with the rules of Appendices XIII and XIV for those parts which do not satisfy the conditions. The rules of Condition A or Condition B are applicable to all integral parts of the vessel, including integrally reinforced type nozzles. For vessels having pad-type nozzles or nonintegral attachments, the requirements of NC-3219.3 apply.

Condition A

Fatigue analysis is not mandatory for materials having a specified minimum tensile strength not exceeding 80.0 ksi (552 MPa) when the total of the expected number of cycles of types (a) plus (b) plus (c) plus (d), defined below, does not exceed 1000 cycles:

(a) is the expected design number of full range pressure cycles including startup and shutdown;

(b) is the expected number of service pressure cycles in which the range of pressure variation exceeds 20% of the Design Pressure. Cycles in which the pressure variation does not exceed 20% of the Design Pressure are not limited in number. Pressure cycles caused by fluctuations in atmospheric conditions need not be considered;

(c) is the effective number of changes in metal temperature² between any two adjacent points³ in the pressure vessel, including nozzles. The effective number of such changes is determined by multiplying the number of changes in metal temperature of a certain magnitude by the factor given in the following table, and by adding the resulting numbers. The factors are as follows:

Metal Temperature Differential,

°F	Factor
50 or less	0
51 to 100	1
101 to 150	2
151 to 250	4
251 to 350	8
351 to 450	12
Excess of 450	20

(For example: Consider a design subjected to metal temperature differentials for the following number of times:

² Thermal protection devices, such as thermal sleeves in nozzles, may be used to reduce temperature differences or thermal shock.

³ Adjacent points are defined in (a) and (b) below.

(a) For surface temperature differences:

(1) on surfaces of revolution, in the meridional direction, adjacent points are defined as points which are less than the distance $2\sqrt{Rt}$, where R is the radius measured normal to the surface from the axis of rotation to the midjoint wall, and t is the thickness of the part at the point under consideration; if the product of Rt varies, the average value of the points shall be used;

(2) on surfaces of revolution, in the circumferential direction and on flat parts (such as flanges and flat heads) adjacent points are defined as any two points on the same surface.

(b) For through-thickness temperature differences, adjacent points are defined as any two points on a line normal to any surface.

Page 71

ΔT , °F	Cycles
50	1000
90	250
400	5

the effective number of changes in metal temperature is

$$1000 (0) + 250 (1) + 5 (12) = 310$$

The number used as type (c) in performing the comparison with 1000 is then 310. Temperature cycles caused by fluctuations in atmospheric conditions need not be considered.)

(d) for vessels with welds between materials having different coefficients of expansion, is the number of temperature cycles which causes the value of $(\alpha_1 - \alpha_2) \Delta T$ to exceed 0.00034 where α_1 and α_2 are the mean coefficients of thermal expansion (Tables TE, Section II, Part D, Subpart 2) and ΔT is the operating temperature range, °F. This does not apply to cladding.

Condition B

Fatigue analysis is not mandatory when all of the conditions of (a) through (f) below are met.

(a) The expected design number of full range pressure cycles, including startup and shutdown, does not exceed the number of cycles in the applicable fatigue curve of Appendix XIV corresponding to an S_a value of 3 times the S_m value in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 for the material at the service temperature.

(b) The expected design range of pressure cycles during normal service⁴ does not exceed the quantity $(\frac{1}{3})$ times the Design Pressure times S_d/S_m , where S_d is the value obtained from the applicable fatigue curve of Appendix XIV for the specified number of significant pressure fluctuations, and S_m is the design stress intensity value found in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 for the service temperature. If the specified number of significant pressure fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_d value corresponding to the maximum number of cycles defined on the curve may be used. Significant pressure fluctuations are those for which the range exceeds the quantity: Design Pressure times $(\frac{1}{3})$ times S/S_m , where S is defined as follows.

(1) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

⁴ Normal service is defined as any set of service conditions other than startup and shutdown which are specified for the vessel to perform its intended function.

(2) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(c) The temperature difference in °F between any two adjacent points of the vessel during normal service and during startup and shutdown does not exceed $S_d/(2E\alpha)$, where S_d is the value obtained from the applicable design fatigue curve for the specified number of startup and shutdown cycles, and α is the value of the instantaneous coefficient of thermal expansion at the mean value of the temperature at the two points, as given by Tables TE, Section II, Part D, Subpart 2. E is taken from Tables TM, Section II, Part D, Subpart 2 at the mean value of the temperatures at the two points.

(d) The range of temperature difference in °F between any two adjacent points of the vessel does not change during normal service by more than the quantity $S_d/(2E\alpha)$, where S_d is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature difference fluctuations. A temperature difference fluctuation shall be considered to be significant if its total algebraic range exceeds the quantity $S/2E\alpha$, where S is defined as follows.

(1) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(2) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(e) For components fabricated from materials of differing moduli of elasticity or coefficients of thermal expansion, the total algebraic range of temperature fluctuation in °F experienced by the vessel during normal service does not exceed the magnitude $S_d/[2(E_1\alpha_1 - E_2\alpha_2)]$, where S_d is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature fluctuations, E_1 and E_2 are the moduli of elasticity, and α_1 and α_2 are the value of the instantaneous coefficients of thermal expansion at the mean temperature value involved for the two materials of construction (Tables TE, Section II, Part D, Subpart 2 and TM, Section II, Part D, Subpart 2). A temperature fluctuation shall be considered to be significant if its total excursion exceeds the quantity $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S is defined as follows.

(1) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

Page 72

(2) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve. If the two materials used have different applicable design fatigue curves, the lower value of S_d shall be used in applying the rules of this paragraph. This does not apply to cladding.

(f) The specified full range of mechanical loads, excluding pressure but including piping reactions, does not result in load stress intensities whose range exceeds the S_d value obtained from the applicable design fatigue curve for the total specified number of significant load fluctuations. If the total specified number of significant load fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_d value corresponding to the maximum number of cycles defined on the curve may be used. A load fluctuation shall be considered to be significant if the total excursion of load stress intensity exceeds the quantity S , where S is defined as follows.

(1) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(2) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

NC-3219.3 Rules to Determine Need for Fatigue Analysis of Nozzles With Separate Reinforcement and Nonintegral Attachments.

A fatigue analysis of pad-type nozzles and nonintegral attachments need not be made, provided *all* of Condition AP or *all* of Condition BP is met. The rules of Condition AP are applicable only to vessels constructed of materials covered by Figs. XIV-1221.3(c)-1, XIV-1221.3(c)-2, and XIV-1221.3(c)-3. If neither Condition AP nor BP is met, a detailed fatigue analysis must be made in accordance with the rules of Appendices XIII and XIV. NC-3237 gives further limitations on pad-type nozzles.

Condition AP

Fatigue analysis of pad-type nozzles and nonintegral attachments is not mandatory for materials having specified minimum tensile strength not exceeding 80.0 ksi (552 MPa) when the total of the expected number of cycles of types (a) plus (b) plus (c) plus (d), defined below, does not exceed 400:

(a) is the expected design number of full range pressure cycles including startup and shutdown;

(b) is the expected number of service pressure cycles in which the range of pressure variation exceeds 15% of the Design Pressure. Cycles in which the pressure variation does not exceed 15% of the Design Pressure are not limited in number. Pressure cycles caused by fluctuations in atmospheric conditions need not be considered.

(c) is the effective number of changes in metal temperature² between any two adjacent points⁵ in the pressure vessel, including nozzles. In calculating the temperature difference between adjacent points, conductive heat transfer shall be considered only through welded or integral cross sections with no allowance for conductive heat transfer across unwelded contact surfaces. The effective number of changes is determined by multiplying the number of changes in metal temperature of a certain magnitude by the factor, given in the following table, and by adding the resulting numbers. The factors are as follows:

Metal Temperature Differential,

°F	Factor
50 or less	0
51 to 100	1
101 to 150	2
151 to 250	4
251 to 350	8
351 to 450	12
Excess of 450	20

(For example: Consider a design subjected to metal temperature differentials for the following number of times:

ΔT , °F	Cycles
50	1000
90	250
400	5

the effective number of changes in metal temperature is

$$1000 (0) + 250 (1) + 5 (12) = 310$$

The number used as type (c) in performing the comparison with 1000 is then 310. Temperature cycles caused by fluctuations

in atmospheric conditions need not be considered.)

5 Adjacent points are defined as points which are spaced less than the distance $2\sqrt{Rt}$ from each other, where R and t are the mean radius and thickness, respectively, of the vessel, nozzle, flange, or other part in which the points are located.

(d) for vessels with welds between materials having different coefficients of expansion, is *the number of temperature cycles* which causes the value of $(\alpha_1 - \alpha_2) \Delta T$ to exceed 0.00034, where α_1 and α_2 are the mean coefficients of thermal expansion (Tables TE,

Page 73

Section II, Part D, Subpart 2) and ΔT is the service temperature range, °F. This does not apply to cladding.

Condition BP

All of the requirements of NC-3219.2, Condition B, are met using the adjusted values in (a) through (c) below.

(a) Use a value of 4 instead of 3 in Condition B(a).

(b) Use a value of one-quarter instead of one-third in Condition B(b).

(c) Use a value of 2.7 instead of 2 in the denominator of Conditions B(c), B(d), and B(e).

NC-3220 DESIGN CONSIDERATIONS

NC-3221 Design Loadings

The provisions of NC-3210 apply.

NC-3222 Special Considerations

The provisions of NC-3121 and NC-3214 apply.

NC-3223 General Design Rules

NC-3223.1 General Requirements.

The design shall be such that the design rules of NC-3200 are satisfied for all configurations and loadings, using the design stress intensity values S_m of Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 in the various formulas.

NC-3223.2 Design Reports.

The Certificate Holder shall provide a Design Report conforming to the requirements of NC-3211.1(e).

NC-3224 Vessels and Parts Under Internal Pressure

NC-3224.1 General Requirements.

The thickness of vessels and parts under internal pressure shall be not less than that computed by the formulas in the following paragraphs. In addition, provision shall be made for the applicable load combinations listed in NC-3218 in establishing the value of F as defined below.

NC-3224.2 Nomenclature.

The symbols used are defined below. Except for test conditions, dimensions used or calculated shall be in the corroded condition.

t	= minimum required thickness of shell, in.
P	= internal pressure at the top of vessel plus any pressure due to the static head of the fluid, at any point under consideration,

	psi
R	= inside radius of the shell under consideration, in. This radius is measured normal to the surface from the axis of revolution.
R_L	= radius of a cylinder at the large end of a cone to cylinder junction, in.
R_s	= radius of a cylinder at the small end of a cone to cylinder junction, in.
α	= one-half of the apex angle of a cone to cylinder junction
t_r	= Q times the required thickness of a cylinder calculated in accordance with NC-3224.13(b)(6)(b), in.
Q	= a factor in the formulas for cone to cylinder junctions depending on P/S and α
r	= inside knuckle radius of torispherical and toriconical heads, in.
S	= membrane stress intensity limit from Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 multiplied by the stress intensity factor in Table NC-3217-1 = kS_m lb/sq in.
D	= inside diameter of a head skirt or inside length of the major axis of an ellipsoidal head or inside diameter of a conical head at the point under consideration measured perpendicular to the axis of revolution, in.
F	= meridional membrane force in the shell wall at the point under consideration resulting from primary loadings other than internal pressure, lb/in. length of circumference. If this force is not uniform, as when resulting from wind or earthquake moment loading, the loading requiring the greatest shell thickness shall be used where the tensile load is positive.
h	= one-half the length of the minor axis of an ellipsoidal head or the inside depth of an ellipsoidal head, measured from the tangent line, in.
k	= stress intensity factor for design, service, and test load combination from Table NC-3217-1
L	= inside spherical or crown radius of torispherical and hemispherical heads, in.

NC-3224.3 Minimum Thickness of Cylindrical Shells.

The minimum thickness of cylindrical shells shall be the greatest of the thicknesses determined by (a), (b), and (c) below.

(a)

$$t = \frac{PR}{S - 0.5P}$$

If $P > 0.4S$, the following equation must be used:

Page 74

$$\ln \frac{(R + t)}{R} = \frac{P}{S}$$

where $\ln$ is the natural log.

(b) If F is positive and exceeds $0.5PR$,

$$t = \frac{0.5PR + F}{S - 0.5P}$$

(c) If F is negative, the condition of axial structural instability or buckling shall be considered separately (see NC-3245).

NC-3224.4 Minimum Thickness of Spherical Shells.

The minimum thickness of spherical shells shall be the greatest of the thicknesses determined by (a), (b), and (c) below.

(a)

$$t = \frac{0.5PR}{S - 0.25P}$$

If $P > 0.4S$, the following equation may be used:

$$\ln \frac{(R + t)}{R} = \frac{0.5P}{S}$$

(b) If F is positive,

$$t = \frac{0.5PR + F}{S - 0.25P}$$

(c) If F is negative, the condition of instability shall be considered. NC-3245 for cylinders may be used for spheres, provided biaxial compression does not exist.

NC-3224.5 Minimum Thickness of Formed Heads.

The minimum thickness at the thinnest point after forming of ellipsoidal, torispherical, and hemispherical heads under pressure acting against the concave surface shall be determined by the appropriate rule or formula in the following subparagraphs.

6 The head design curves have been developed considering membrane stress requirements, plastic collapse, cyclic load conditions, and the effects of maximum allowable tolerances in accordance with NC-4222. See A-4000 of Appendix A for the design formulas for the curves of Fig. NC-3224.6-1.

7 Heads having $D/2h = 2$ have equivalent torispherical properties of a torisphere of $LD = 0.90$ and $r/D = 0.17$.

NC-3224.6 Minimum Thickness of Ellipsoidal Heads.^{6,7}

The minimum thickness of a 2:1 ellipsoidal head shall be established using the procedures given in NC-3224.8 and the curve of Fig. NC-3224.6-1 which is labeled "2:1 ellipsoidal head." Ellipsoidal head designs which have $D/2h$ values

different from 2 shall be analyzed as equivalent torispherical heads or according to Appendix II, XIII, or XIV. The cylindrical shell to which the head is attached shall be equal to or greater in thickness than the required head thickness for a distance, measured from the tangent line along the cylinder, of not less than $\sqrt{Rt}$. Transition joints to shells of thickness less than the required head thickness shall not be located within the minimum distance. Transition joints to shells of thickness greater than the required head thickness may be located within this minimum distance and shall be in accordance with NC-3361 and Fig. NC-3358-1.

NC-3224.7 Minimum Thickness of Hemispherical Heads.

For hemispherical heads, the thickness shall be as required for spherical shells, NC-3224.4. The requirements for the transition to cylindrical shells of different thickness, given in NC-3361 and Fig. NC-3361-1, shall be met.

NC-3224.8 Minimum Thickness of Torispherical Heads.⁷

The minimum thickness of a torispherical head having $t/L \geq 0.002$ up to a t/L where $P/S \leq 0.08$ (approximately $t/L = 0.04$ to 0.05) shall be established by using the curves in Fig. NC-3224.6-1. Interpolation may be used for r/D values which fall within the range of the curves; however, no extrapolation of the curves is permitted. For designs where $P/S > 0.08$, which is above the upper limit of Fig. NC-3224.6-1, the thickness shall be set by the following formula:

$$t = \frac{D}{2} (e^{P/S} - 1)$$

Where $t/L < 0.002$, which is below the lower limit of Fig. NC-3224.6-1, the head design must be analyzed according to Appendix II, XIII, or XIV. The cylindrical shell to which the head is attached shall be equal to or greater in thickness than the required head thickness for a distance, measured from the tangent line along the cylinder, of not less than $\sqrt{Rt}$. Transition joints to shells of thickness less than the required head thickness shall not be located within this minimum distance. Transition joints to shells of thickness greater than the required head thickness may be located within this minimum distance and shall be in accordance with NC-3361 and Fig. NC-3358-1.

NC-3224.8.1 Crown and Knuckle Radii.

In connection with the design procedures of NC-3224.8 and Fig. NC-3224.6-1, the inside crown radius to which

Page 75

an unstayed head is formed shall not be greater than the inside diameter of the skirt of the head. The inside knuckle radius of a torispherical head shall not be less than 6% of the outside diameter of the skirt nor less than three times the head thickness.

[98]

FIG. NC-3224.6-1 DESIGN CURVES FOR TORISPHERICAL HEADS AND 2:1 ELLIPSOIDAL HEADS

NC-3224.9 Minimum Thickness of Integral Head Skirts.

In addition to the requirements of NC-3224.8 or NC-3224.6, when an integral head skirt is provided, the skirt thickness shall not be less than the required thickness of a seamless shell of the same diameter. All transition joints shall be in accordance with NC-3361 and Fig. NC-3358-1.

NC-3224.10 Composite Head Shapes.

A head for a cylindrical shell may be built up of several head shapes, the thicknesses of which satisfy the requirements of the appropriate formulas above. The adjoining shapes must be so formed that they have a common tangent transverse to the joint. Any taper at a joint shall be within the boundary of the shape having the thinner wall (Fig. NC-3361-1).

NC-3224.11 Loadings on Heads Other Than Pressure.

Provision shall be made for other loadings given in NC-3212. For torispherical and ellipsoidal heads, the effect of other loadings must be determined in accordance with Appendix II, XIII, or XIV. For the conical or spherical portions of heads, the effect of composite loading may be treated as in NC-3224.3, NC-3224.4, and NC-3224.13(a)(4).

NC-3224.12 Toriconical Heads.

(In preparation.)

NC-3224.13 Reducer Sections

(a) General Requirements

(1) *Applicable Formulas and Rules.* These rules apply to concentric reducer sections when all the longitudinal loads are transmitted wholly through the shell of the reducer. When loads are transmitted in part or as a whole by other elements, such as inner shells, stays, or tubes, these rules do not apply.

(2) *Minimum Thickness of Reducer Elements.* The thickness of each element of a reducer under internal pressure shall not be less than that computed by the applicable formula. In addition, provisions shall be made for any of the other loadings listed in NC-3212.

(3) *Transition Section Reducers Joining Two Cylindrical Shells.* A transition section reducer consisting of one or more elements may be used to join two cylindrical shell sections of different diameters but with a common axis, provided these requirements are met.

(4) *Minimum Thickness of Conical Shells.* The minimum thickness of conical shells shall be determined by the same formulas as for cylindrical shells in which R is the radius measured normal to the wall surface at the point under consideration. NC-3224.13(b) and NC-3224.13(c) give rules for cone to cylinder junctions of the large and small end, respectively.

(a)

$$t = \frac{PR}{S - 0.5P}$$

If $P > 0.4S$,

$$\ln \frac{(R + t)}{R} = \frac{P}{S}$$

(b) If F is positive and exceeds $0.5 PR$,

$$t = \frac{0.5PR + F}{S - 0.5P}$$

(c) If F is negative, the condition of axial structural instability or buckling must be considered separately. NC-3245 for cylinders may be used for conical sections.

(5) *Knuckle Tangent to the Larger Cylinder.* When a knuckle is used at the large end of a reducer section, it shall have a shape that is a portion of an ellipsoidal, hemispherical, toriconical, or torispherical head. The thickness and other dimensions shall satisfy the requirements of NC-3224.5.

(6) *Combination of Elements to Form a Reducer.* When elements having different thicknesses are combined to form a reducer, the joints including the plate taper shall lie entirely within the limits of the thinner element being joined.

(7) *Combination of Shapes to Form a Toriconical Reducer.* A toriconical reducer may be shaped as a portion of a toriconical head or a portion of an ellipsoidal head plus a conical section, provided the design of the small end of the reducer element satisfies the requirements of NC-3224.13(c).

(b) *Supplementary Requirements for Reducer Sections and Conical Heads, Large End.* These rules apply, provided the requirements of (1) through (6) below are met:

(1) the two parts to be joined have the same rotational axis;

(2) the load is internal pressure (see NC-3224.11);

(3) the joint is a butt weld having its surfaces merge smoothly, both inside and outside, with the adjacent cone and cylinder surfaces without reducing the thickness [NC-3252.2(b)];

Page 77

(4) the weld at the junction is radiographed and meets the requirements of NC-5250;

(5) the junction is not closer than $4\sqrt{R_L \times t_r}$ to another junction or major discontinuity;

(6) *Reinforcement Requirements:*

(a) *When Inherent Reinforcement Is Adequate.* The thickness of the cone and cylinder forming a junction at the large end for half apex angles up to 30 deg. need not be thicker than required by NC-3224.3 or NC-3224.13(a)(4)(a), if the point representing the junction lies in the Adequate region of Fig. NC-3224.13(b)(6)(a)-1.

(b) *Requirements for Integral Reinforcement.* When the half-apex angle exceeds the maximum permitted by Fig. NC-3224.13(b)(6)(a)-1, the cone and cylinder must be reinforced in the area adjacent to the junction. Figure NC-3224.13(b)(6)(b)-1 gives Q values for ratios of Design Pressure P to S and values of α up to 30 deg. The junction may be reinforced by making both the cylinder and cone thickness equal to t_r and provided that the requirements of

(1) through (3) below are met.

(1) The increased cylinder thickness extends a minimum distance of $2.0\sqrt{R_L t_r}$ from the junction, where R_L is the radius of the cylinder at the large end of the cone.

(2) The increased cone thickness extends a minimum distance of $2.0\sqrt{R_L t_r / \cos \alpha}$ from the junction.

(3) In no case shall t be less than the thickness required for the cone in accordance with NC-3224.3.

(c) *Supplementary Requirements for Reducer Section's Small End.* These rules apply, provided the requirements of (1) through (6) below are met:

(1) the two parts to be joined have the same rotational axis;

(2) the load is internal pressure (NC-3224.11);

(3) the joint is a butt weld having its surfaces merge smoothly, both inside and outside, with the adjacent cone and cylinder surfaces without reducing the thickness [NC-3252.2(b)];

(4) the weld at the junction is radiographed and meets the requirements of NC-5250;

(5) the junction is not closer than $2.8\sqrt{R_s t_r}$ to another junction or discontinuity, where R_s is the radius of the cylinder at the small end of the cone;

(6) *Reinforcement Requirements:*

(a) *When Inherent Reinforcement Is Adequate.* The thickness of the cone and cylinder forming a junction at the small end of half apex angles up to 30 deg. need not be thicker than required by NC-3224.3 if the point representing the junction lies in the Adequate region of Fig. NC-3224.13(c)(6)(a)-1.

(b) *Requirements for Integral Reinforcement.* When the half apex angle exceeds the maximum permitted by Fig. NC-3224.13(c)(6)(a)-1, the cone and cylinder must be reinforced in the area adjacent to the junction. Figure NC-3224.13(c)(6)(b)-1 gives Q values for ratios of Design Pressure P to S and values of α up to 30 deg. The junction may be reinforced by making both the cylinder and cone thickness equal to t_r and provided that the requirements of (1) through (3) below are met.

(1) The increased cylinder thickness t_r extends a minimum distance $1.4\sqrt{R_s t_r}$ from the junction.

(2) The increased cone thickness t_r extends a minimum distance $1.4\sqrt{R_s t_r / \cos \alpha}$ from the junction.

(3) In no case shall t_r be less than the thickness required for the cone in accordance with NC-3224.3 at a distance $1.4\sqrt{R_s t_r / \cos \alpha}$ from the junction.

(d) *Supplementary Requirements for Reducer Sections, Small End, Treated As Openings.* Cone to cylinder junctions at the small ends of reducers as shown in Fig. NC-3224.13(d)-1 may be treated as openings in conical heads provided the requirements of (1) through (4) below are met.

(1) The diameter d of the small end is not more than one-half the diameter of the large end.

(2) The half apex angle α is greater than 30 deg. but not greater than 60 deg.

(3) The reinforcement meets the requirements of NC-3232 and NC-3234.1, except that the total cross-sectional area of reinforcement A required at the junction in any plane for a vessel under internal pressure shall not be less than $A = dt \tan \alpha/2$ and two-thirds of this area shall be provided within a limit of $0.5 \sqrt{dt/2}$ measured along the cylinder and $0.5 \sqrt{dt / 2 \cos^2 \alpha}$ measured along the cone.

(4) Reinforcement shall be integral with cone or cylinder and all other applicable requirements of NC-3230 are met.

NC-3224.14 Minimum Thickness of Nozzle Necks and Other Connections.

The wall thickness of a nozzle neck or other connection shall not be less than the thickness computed for the applicable loadings plus the thickness added for corrosion and erosion allowance and, except for access openings and openings for inspection only, not less than the smaller of (a) and (b) below:

(a) the required thickness of the shell or head to which the connection is attached plus the corrosion allowance provided in the shell or head adjacent to the connection;

FIG. NC-3224.13(b)(6)(a)-1 INHERENT REINFORCEMENT FOR LARGE END OF CONE-CYLINDER JUNCTION

FIG. NC-3224.13(b)(6)(a)-1 INHERENT REINFORCEMENT FOR LARGE END OF CONE-CYLINDER JUNCTION

(b) the minimum thickness⁸ of standard wall pipe plus the corrosion allowance on the connections.

NC-3224.15 Other Loadings.

When necessary, vessels shall be provided with stiffeners or other additional means of support to prevent overstress or large distortions under the external loadings listed in NC-3111 other than pressure and temperature.

NC-3225 Flat Heads and Covers

The minimum thickness of unstayed flat heads, cover plates, and blind flanges shall conform to the requirements given in this paragraph. Some acceptable types of flat heads and covers are shown in Fig. NC-3225-2. The dimensions are exclusive of extra metal added for corrosion allowance.

⁸ The minimum thickness for all pipe materials is the nominal thickness listed in Table 2 of ANSI B36.10 less $12\frac{1}{2}\%$. For diameters other than those listed in the table, the minimum thickness shall be that of the next larger pipe size.

NC-3225.1 Nomenclature.

The notations used are defined as follows:

C	= a factor depending upon the method of attachment of head, shell dimensions, and other items as listed in NC-3225.2, dimensionless (Figs. NC-3225-1 through NC-3225-3)
d	= diameter, in.
D	= bolt circle diameter, in.
h_G	= gasket moment arm, equal to the radial distance from the center line of the bolts to the line of the gasket reaction, in. (Fig. NC-3225-2)
L	= distance from center line of head to shell weld to tangent line on formed heads, in., as indicated in Fig. NC-3225-2 sketch (a)
m	= the ratio t_r/t_s , dimensionless
P	= Design Pressure, psi
r	= inside corner radius on a head formed by flanging or forging, in.
S	= design stress intensity S_m from Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 multiplied by tabulated stress intensities, psi

Page 79

FIG. NC-3224.13(b)(6)(b)-1 VALUES FOR Q FOR SMALL END OF CONE-CYLINDER JUNCTION

T	= minimum required thickness of flat head, cover, or flange, exclusive of corrosion allowance, in.
t_f	= actual thickness of the flange on a formed head, at the large end, exclusive of corrosion allowance, in.
t_p	= the smallest dimension from the face of the head to the edge of the weld preparation, in.
t_r	= required thickness of shell or nozzle for pressure, in.
t_s	= actual thickness of shell or nozzle, in.
W	= total bolt load, lb

FIG. NC-3224.13(c)(6)(a)-1 INHERENT REINFORCEMENT FOR SMALL END OF CONE-CYLINDER JUNCTION

FIG. NC-3224.13(c)(6)(a)-1 INHERENT REINFORCEMENT FOR SMALL END OF CONE-CYLINDER JUNCTION

NC-3225.2 Formulas for Minimum Thickness⁹

(a) The thickness of flat heads, as shown in Figs. NC-3225-1 through NC-3225-3, shall be not less than that calculated by the following equation:

$$T = d\sqrt{CP/S}$$

(b) The thickness of cover plates and blind flanges attached by bolts causing an edge moment as shown in Fig. NC-3225-2 shall be not less than that calculated by the following equation:

⁹ The formulas provide safe construction as far as stress is concerned. Greater thicknesses may be necessary if deflection would cause leakage at threaded or gasketed joints.

$$T = d\sqrt{CP/S + 1.27 Wh/Sd^3}$$

NOTE: In some cases, the initial bolt load required to seat the gasket is larger than the service bolt load. The thickness should be checked for both the service condition and the initial bolt load required to seat the gasket.

NC-3227 Quick Actuating Closures

The requirements for quick actuating closures are given in NC-3327.

NC-3230 OPENINGS AND THEIR REINFORCEMENT

NC-3231 General Requirements

The rules contained in this Subarticle provide for a satisfactory design in the vicinity of openings in the pressure shell, under pressure loading only, on the basis of its opening shape, area replacement, and distribution, provided a fatigue analysis is not required. These rules do not include design requirements for piping loads that may be imposed on the nozzle or shell portion

Page 81

or both and that may be added to the pressure loadings. Such additional loadings shall be considered by the designer.

FIG. NC-3224.13(c)(6)(b)-1 VALUES FOR Q FOR SMALL END OF CONE-CYLINDER JUNCTION

FIG. NC-3224.13(c)(6)(b)-1 VALUES FOR Q FOR SMALL END OF CONE-CYLINDER JUNCTION

FIG. NC-3224.13(d)-1 CONE-CYLINDER JUNCTION AT SMALL END TREATED AS OPENING

FIG. NC-3224.13(d)-1 CONE-CYLINDER JUNCTION AT SMALL END TREATED AS OPENING

NC-3231.1 Dimensions and Shape of Openings

(a) Openings, except as permitted under (b), shall be circular, elliptical, or of any other shape which results from the intersection of a circular or elliptical cylinder with vessels of the shapes for which formulas are given in NC-3220, provided the requirements of (1) through (4) below are met.

(1) The ratio of the diameter along the major axis to the diameter along the minor axis of the finished opening is 1.5 or less.

(2) The ratio $d/D \leq 0.50$ where d is the largest inside diameter of the intersecting nozzle and D is the inside diameter of the vessel.

(3) The arc distance measured between the center lines of adjacent nozzles along the inside surface of the shell is not less than three times the sum of their inside radii for openings in a head or for openings along the longitudinal axis of a shell and is not less than two times the sum of their inside radii for openings along the circumference of a cylindrical shell. When two nozzles in a cylindrical shell are neither in a longitudinal line nor in a circumferential arc, their center line distance along the inside surface of the shell shall be such that $[(L_c/2)^2 + (L_c/3)^2]^{1/2}$ is not less than the sum of their inside radii, where L_c is the component of the center line distance in the circumferential direction and L is the

component of the center line distance in the longitudinal direction.

(4) Reinforcement is provided around the edge of the opening in amount and distribution such that the area requirements for reinforcement are satisfied for all planes through the center of the opening and normal to the vessel surface as stipulated in NC-3232.2.

(b) Openings of other shapes or dimensions may be used subject to the requirements of Appendix XIII or Appendix XIV.

(c) Any type of opening permitted by these rules may be located in a butt welded joint.

Page 83

Page 84

FIG. NC-3225-2 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

FIG. NC-3225-2 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

NC-3232 Reinforcement Requirements for Openings in Shells and Formed Heads

NC-3232.1 Circular Openings Not Requiring Reinforcement.

Circular openings need not be provided with reinforcement if all the requirements in (a), (b), and (c) below are satisfied.

(a) A single opening has a diameter not exceeding $0.2\sqrt{Rt}$, or if there are two or more openings within any circle of diameter, $2.5\sqrt{Rt}$, then the sum of the diameters of such unreinforced openings shall not exceed $0.25\sqrt{Rt}$.

(b) No two unreinforced openings shall have their centers closer to each other, measured on the inside of the vessel wall, than 1.5 times the sum of their diameters.

(c) No unreinforced opening shall have its center closer than $2.5\sqrt{Rt}$ to the edge of a locally stressed area in the shell where R is the mean radius and t is the nominal thickness of the vessel shell or head at the location of the openings and where locally stressed area means any area in the shell where the primary local membrane stress exceeds $1.1kS_m$, but excluding those areas where such primary local membrane stress is due to an unreinforced opening.

excluding those areas where such primary local membrane stress is due to an unreinforced opening.

NC-3232.2 Required Area of Reinforcement

(a) The total cross-sectional area of reinforcement A required in any given plane for a vessel under internal pressure shall be not less than

$$A = dt_r F$$

where

d

= finished diameter of a circular opening or finished dimension (chord length) of an opening on the plane being considered for elliptical and obround openings in corroded condition, in.

t_r

= the thickness which meets the requirements of NC-3220 in the absence of the opening, in.

F

= 1.00 when the plane under consideration is in the spherical portion of a head or when the given plane contains the longitudinal axis of a cylindrical shell. For other planes through a shell, use the value of F determined from Fig. NC-3332.2-1 except that, for reinforcing pads, $F = 1$.

$C \text{ min.} = 0.7 t_s \text{ or } 1/4 \text{ in., whichever is less}$
 $b = \text{the lesser of } t_s \text{ or } T/2$

FIG. NC-3225-3 ATTACHMENT OF PRESSURE PARTS TO PLATES TO FORM A CORNER JOINT

FIG. NC-3225-3 ATTACHMENT OF PRESSURE PARTS TO PLATES TO FORM A CORNER JOINT

(b) Not less than one-half the required material shall be on each side of the center line of the opening [NC-3234.1(c)].

NC-3233 Required Reinforcement for Openings in Flat Heads

(a) Flat heads that have an opening with a diameter that does not exceed one-half of the head diameter shall have a total cross-sectional area of reinforcement not less than that given by the formula

$$A = 0.5dt_r$$

where

d = the diameter of the finished opening in its corroded condition, in.

t_r = the thickness which meets the requirements of NC-3225.2 in the absence of the opening, in.

(b) Flat heads that have an opening with a diameter that exceeds one-half of the head diameter shall be designed according to Appendix XIX.

NC-3234 Limits of Reinforcement

The boundaries of the cross-sectional area in any plane normal to the vessel wall and passing through the center of the opening within which metal shall be located in order to have value as reinforcement are designated as the limits of reinforcement for that plane and are as described in the following subparagraphs.

NC-3234.1 Limit of Reinforcement Along the Vessel Wall.

The limits of reinforcement, measured along the midsurface of the nominal wall thickness of the vessel, shall meet the following:

(a) 100% of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) the diameter of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus the sum of the thicknesses of the vessel wall and the nozzle wall;

(b) two-thirds of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) $r + 0.5\sqrt{Rt}$, where R is the mean radius of shell or head, t is the nominal vessel wall thickness, r is the radius of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus two-thirds the sum of the thicknesses of the vessel wall and the nozzle wall.

NC-3234.2 Limit of Reinforcement Normal to Vessel Wall.

The limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to the limits given in (a), (b), and (c) below.

(a) For Fig. NC-3234.2(a)-1 sketches (a) and (b), the limit is the larger of $(0.5\sqrt{r_m t_n} + k)$ or $(1.73x + 2.5t_p + k)$, but not to exceed either $2.5t$ or $(L + 2.5t_p)$.

Where

r = inside radius of nozzle

t_n	= nominal nozzle thickness
r_m	= mean nozzle radius = $r + 0.5t_n$
r_2	= transition radius between nozzle and wall
t_p	= nominal thickness of connecting pipe
t	= nominal vessel wall thickness
L	= length along nozzle with thickness of t_n plus transition length
k	= $0.73r_2$ when a transition radius (r_2) is used = the smaller of two legs of the fillet when a fillet transition is used
x	= $t_n - t_p$

(b) For Fig. NC-3234.2(a)-1 sketch (c), when $45 \geq \theta \geq 30$ deg., the limit is the larger of $(0.5\sqrt{r_m t_n})$ or $(L' + 2.5t_p)$, but not to exceed $2.5t$; when $\theta < 30$ deg., the limit is the larger $(0.5\sqrt{r_m t_n})$ or $(1.73x + 2.5t_p)$, but not to exceed $2.5t$. Where

t_n'	= $t_p + 0.667x$
x	= slope offset distance
θ	= angle between vertical and slope
L'	= length of tapered section along nozzle
r_m	= $r + 0.5t_n'$

Other terms are defined in (a) above.

(c) For Fig. NC-3234.2(a)-1 sketch (d), when reinforcing pads or insert plates are used, the limit is the larger of $(0.5\sqrt{r_m t_n} + t_e)$ or $(2.5t_n + t_e)$, but not to exceed $2.5t$. In no case can the thickness t_e used to establish the limit normal to the shell, exceed $1.5t$ or $1.73W$. Where

W	= width of added reinforcing element
t_e	= thickness of added reinforcing element

Other terms are defined in (a) above.

Page 87

Page 88

FIG. NC-3234.2(a)-1 NOZZLE NOMENCLATURE AND DIMENSIONS
Depicts Configuration Only

FIG. NC-3234.2(a)-1 NOZZLE NOMENCLATURE AND DIMENSIONS

NC-3234.3 Nozzle Piping Transitions.

The stress limits of NC-3200 shall apply to all portions of nozzles which lie within the limits of reinforcement given in NC-3234, except as noted in NC-3234.4. Stresses in the extension of any nozzle beyond the limits of reinforcement shall meet the stress limits of NC-3600.

NC-3234.4 Consideration of Standard Reinforcement.

Where a nozzle-to-shell juncture is reinforced in accordance with the rules of NC-3234, the stresses in this region due to internal pressure may be considered to satisfy the limits of NC-3217. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region. Where external piping loads are to be designed for, membrane plus bending stresses shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of NC-3217 for $(P_m \text{ or } P_L) + P_b$. In this case, the pressure induced stresses in the $(P_m \text{ or } P_L) + P_b$ category may be assumed to be no greater than the limit specified for P_m in NC-3217 for a given condition.

NC-3235 Metal Available for Reinforcement

Metal may be counted as contributing to the area of reinforcement called for in NC-3232.2 and NC-3233, provided it lies within the area of reinforcement specified in NC-3234 and shall be limited to material which meets the requirements of (a) through (e) below:

- (a) metal forming a part of the vessel wall which is in excess of that required on the basis of primary stress intensity (NC-3221 through NC-3224 and NC-3225.2) and is exclusive of corrosion allowance;
- (b) similar excess metal in the nozzle wall, provided the nozzle is integral with the vessel wall or is joined to it by a full penetration weld;
- (c) weld metal which is fully continuous with the vessel wall;
- (d) metal not fully continuous with the shell, such as a pad continuously welded around its periphery, may be counted as reinforcement, provided the requirements of NC-4237 are met;
- (e) the mean coefficient of thermal expansion of metal to be included as reinforcement under (b), (c), and (d) above shall be within 15% of the value for the metal in the vessel wall.

NC-3235.1 Metal Not Available for Reinforcement.

Metal not fully continuous with the shell, as that in nozzles attached by partial penetration welds, shall not be counted as reinforcement.

NC-3235.2 Reinforcement Metal Limited to One Opening.

Metal available for reinforcement shall not be considered as applying to more than one opening.

NC-3236 Strength of Reinforcement Material

Material used for reinforcement shall preferably have the same design stress intensity value as that of the vessel wall. In no case shall material with an allowable design stress intensity value less than 80% of the value of the vessel wall material at the Design Temperature be used in determining area available for reinforcement. If the material of the nozzle wall or reinforcement has a lower design stress intensity value S_m than that for the vessel material, the amount of area provided by the nozzle wall or reinforcement in satisfying the requirements of NC-3232 shall be taken as the actual area provided multiplied by the ratio of the nozzle or reinforcement design stress intensity value to the vessel material design stress intensity value. No reduction in the reinforcement requirement may be made if the reinforcing material or weld metal has a design stress intensity value higher than that of the material of the vessel wall. The strength of the material at the point under consideration shall be used in fatigue analyses.

NC-3237 Requirements for Nozzles With Separate Reinforcing Plates

Except for nozzles at small ends of cones reinforced in accordance with the requirements of NC-3224.11(c), added reinforcement in the form of separate reinforcing plates may be used, provided the vessel and the nozzles meet all the conditions of (a) through (d) below.

- (a) The specified minimum tensile strengths of the materials do not exceed 80 ksi (552 MPa).
- (b) The minimum elongation of materials is 12% in 2 in.
- (c) The thickness of the added reinforcement does not exceed $1\frac{1}{2}$ times the shell thickness.
- (d) The requirements of NC-3219 for pads in cyclic service are met.

NC-3239 Alternative Rules for Opening Reinforcement

The requirements of this paragraph constitute an acceptable alternative to the rules of NC-3231 through NC-3237 and XIII-2000.

[98]

NC-3239.1 Limitations.

These rules are applicable only to openings utilizing nozzles in vessels within the limitations of (a) through (f) below.

Page 89

FIG. NC-3239.1(b)-1 EXAMPLES OF ACCEPTABLE TRANSITION DETAILS

FIG. NC-3239.1(b)-1 EXAMPLES OF ACCEPTABLE TRANSITION DETAILS

- (a) The nozzle is circular in cross section and its axis is perpendicular to the vessel or head.
- (b)

parts. Details such as those shown in Figs. NC-4266(a)-1, NC-4266(b)-1 sketches (a), (b), and (c), and NC-4266(c)-1 are acceptable. However, fillet welds must be ground to a radius in accordance with Fig. NC-3239.1(b)-1.

(c) In the case of spherical shells and formed heads, at least 40% of the total nozzle reinforcement area shall be located beyond the outside surface of the minimum required vessel wall thickness.

(d) The spacing between the edge of the opening and the nearest edge of any other opening is not less than the smaller of $1.25 (d_1 + d_2)$ and $2.5\sqrt{Rt_r}$, but in any case, not less than $1.0 (d_1 + d_2)$, where d_1 and d_2 are the inside diameters of the openings.

(e) The materials used in the nozzle reinforcement and vessel wall adjacent to the nozzle shall have a ratio of UTS/YS of not less than 1.5, where

UTS = specified minimum ultimate tensile strength

YS = specified minimum yield strength

(f) The following dimensional limitations are met:

	Nozzles in Cylindrical Vessels	Nozzles in Spherical Vessels or Heads
D/t	10 to 100	10 to 100
d/D	0.5 max.	0.5 max.
$d/\sqrt{Dt}$	...	0.8 max.
$d/\sqrt{Dt_n} \sqrt{t/t_n}$	1.5 max.	...

[98]

NC-3239.2 Nomenclature

D	= inside diameter, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.
d	= inside diameter of the nozzle in its corroded condition, in.
R	= inside radius, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.
r	= inside radius of the nozzle in its corroded condition, in.
t_r	= wall thickness of vessel or head, computed by the equation given in NC-3224.3 for cylindrical vessels; by NC-3224.4 for spherical vessels or spherical heads, in.
t_{rn}	= wall thickness of nozzle, computed by the equation given in NC-3224.3, in.

Page 90

t	= nominal wall thickness of vessel or head, less corrosion allowance, in.
t_n	= nominal wall thickness of nozzle, less corrosion allowance, in.
A_r	= required minimum reinforcing area, sq in.
A_a	= available reinforcing area, sq. in.

**TABLE NC-3239.3(a)-1
REQUIRED MINIMUM REINFORCING AREA A_r**

Required Minimum Reinforcing Area A_r		
Value of $d/\sqrt{Rt_r}$	Nozzles in Cylinders	Nozzles in Spherical Vessels or Heads
Less than 0.20 and	None [Note (1)]	None [Note (1)]
Greater than 0.20 and less than 0.40	$\{4.05 [d/\sqrt{Rt_r}]^{1/2} - 1.81\} dt_r$	$\{5.40 [d/\sqrt{Rt_r}]^{1/2} - 2.41\} dt_r$
Greater than 0.40	$0.75 dt_r$	$dt_r \cos \phi$ $\phi = \sin^{-1} (d/D)$

NOTE:

(1) The transition radius r_2 shown in Fig. NC-3239.1(b)-1, or equivalent, is required.

TABLE NC-3239.3(a)-1 REQUIRED MINIMUM REINFORCING AREA A_r

See Fig. NC-3239.1(b)-1 for $r_1, r_2, r_3, r_4, r_5, \theta, \theta_1$. See Fig. NC-3239.4-1 for L_c, L_n . See Fig. XIII-2122-1 and NC-3239.7 for $S, \sigma_p, \sigma_n, \sigma_r, \sigma$.

NC-3239.3 Required Reinforcement Area

- (a) The required minimum reinforcing area is related to the value of $d/\sqrt{Rt_r}$ shown in Table NC-3239.3(a)-1.
- (b) The required minimum reinforcing area shall be provided in all planes containing the nozzle axis.

NC-3239.4 Limits of Reinforcing Zone.

Reinforcing metal included in meeting the minimum reinforcing area specified in NC-3239.3 must be located within

the reinforcing zone boundary shown in Fig. NC-3239.4-1.

NC-3239.5 Strength of Reinforcing Material Requirements.

Material in the nozzle wall used for reinforcing should preferably be the same as that of the vessel wall. If material with a lower design stress intensity value S_m is used, the area provided by such material shall be increased in proportion to the inverse ratio of the stress values of the nozzle and the vessel wall material. No reduction in the reinforcing area requirement may be taken for the increased strength of nozzle material or weld metal which has a higher design stress value than that of the material of the vessel wall. The strength of the material at the point under consideration shall be used in fatigue analyses. The mean coefficient of thermal expansion of metal to be included as reinforcement shall be within 15% of the value for the metal of the vessel wall.

NC-3239.6 Transition Details.

Examples of acceptable transition tapers and radii are shown in Fig. NC-3239.1(b)-1. Other configurations which meet the reinforcing area requirements of NC-3239.3 and with equivalent or less severe transitions are also acceptable, such as larger radius-thickness ratios.

NC-3239.7 Stress Indices

(a) The term stress index is defined as the numerical ratio of the stress components σ_r , σ_n , and σ_t under consideration to the computed stress S . The symbols for the stress components are shown in Fig. XIII-2122-1 and are defined as follows:

S	= $P(2R + t)/4t$ for nozzles in spherical vessels or heads, psi
S	= $P(2R + t)/2t$ for nozzles in cylindrical vessels, psi
σ_t	= the stress component in the plane of the section under consideration and parallel to the boundary of the section, psi
σ_n	= the stress component normal to the plane of the section, ordinarily the circumferential stress around the hole in the shell, psi
σ_r	= the stress component normal to the boundary of the section, psi
σ	= the stress intensity, combined stress, at the point under consideration, psi
P	= service pressure, psi

(b) When the conditions of NC-3239.1 through NC-3239.6 are satisfied, the stress indices given in Table NC-3239.7-1 may be used. These stress indices deal only with the maximum stresses, at certain general locations, due to internal pressure. In the evaluation of stresses in or adjacent to vessel openings and connections, it is often necessary to consider the effect of stresses due to external loadings or thermal stresses. In such cases, the total stress at a given point may be determined by superposition. In the case of combined stresses due to internal pressure and nozzle loading, the maximum stresses should be considered as acting at the same point and added algebraically. If the stresses are otherwise determined by more accurate analytical techniques or by the experimental stress analysis procedure of Appendix II, the stresses are also to be added algebraically.

FIG. NC-3239.4-1 LIMITS OF REINFORCING ZONE

FIG. NC-3239.4-1 LIMITS OF REINFORCING ZONE

NC-3240 VESSELS UNDER EXTERNAL PRESSURE

NC-3241 General Requirements

These rules are applicable to spherical and cylindrical shells with or without stiffening rings and to formed heads and to tubular products (NC-4221.2). Charts for use in determining the thicknesses of these components are given in Section II, Part D, Subpart 3.

NC-3241.1 Nomenclature.

The symbols used in this Article are defined below. Except for the test condition, dimensions used or calculated shall be in the corroded condition.

T

= minimum required thickness of the cylindrical or spherical shell or tubular product, exclusive of corrosion allowance, in.

L

= design length of a vessel section, using the applicable

definition below: the distance between head bend lines plus one-third of the depth of each head if there are no stiffening rings; the greatest center to center distance between any two adjacent stiffening rings; or the distance from the center of the first stiffening ring to the head bend line plus one-third of the depth of the head, all measured parallel to the axis of the vessel, in.

R	= inside radius of spherical shells, in.
L_s	= one-half of the distance from the center line of the stiffening ring to the next line of support on one side, plus one-half of the centerline distance to the next line of support, if any, on the other side of the stiffening ring, both measured parallel to the axis of the vessel, in. (A line of support is a stiffening ring that meets the requirements of this paragraph; a circumferential line on a head at one-third the depth of the head from the head bend line; a circumferential connection to a jacket.)
D_o	= outside diameter of the cylindrical shell course under consideration, in.
P	= external Design Pressure, psi
I_s	= required moment of inertia of the combined ring shell section about its neutral axis parallel to the axis of the shell, in. ⁴ The width of shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10 \sqrt{D_o} \bar{T}$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing area to more than one stiffening ring.
A_s	= cross-sectional area of the stiffening ring, sq in.
A	= factor determined from the appropriate chart in Section II, Part D, Subpart 3 for the material used in the stiffening ring, corresponding to the factor B and the Design Temperature for the shell under consideration
B	= factor from the charts in Section II, Part D, Subpart 3, psi

**TABLE NC-3239.7-1
STRESS INDICES FOR INTERNAL
PRESSURE LOADING**

Nozzles in Spherical Shells and Spherical Heads		
Stress	Inside	Outside
σ_n	$2.0 - (r/R)$	$2.0 - (r/R)$
σ_t	-0.2	$2.0 - (r/R)$
σ_r	$-4t_p/(2R + t_p)$	0
σ	larger of: $2.2 - (r/R)$, or $2.0 + [4t_p/(2R + t_p)] - (r/R)$	$2.0 - (r/R)$

Nozzles in Cylindrical Shells				
Stress	Longitudinal Plane		Transverse Plane	
	Inside	Outside	Inside	Outside
σ_n	3.1	1.2	1.0	2.1
σ_t	-0.2	1.0	-0.2	2.6
σ_r	$-2t_p/(2R + t_p)$	0	$-2t_p/(2R + t_p)$	0
σ	3.3	1.2	1.2	2.6

TABLE NC-3239.7-1 STRESS INDICES FOR INTERNAL PRESSURE LOADING

NC-3242 Cylindrical Shells

NC-3242.1 For $D_o/T \geq 10$.

The minimum thickness of pipes or shell under external pressure¹⁰ having D_o/T values equal to or greater than 10 shall be determined by the procedure given in NC-3133.3.

NC-3242.2 For $D_o/T < 10$.

The minimum thickness of pipes or tubes under external pressure having D_o/T values less than 10 shall be determined by the procedure given in Steps 1 through 4 below:

Step 1: Compute a value for factor A from the equation

$$A = 1.1/(D_o/T)^2$$

Step 2: Enter the appropriate chart with the calculated value of A and move vertically to the material line for the Design Temperature or to the horizontal projection of the upper end of this material line where A falls to the right of the end of the material line. From this intersection, move horizontally to the right and read the value of B .

Step 3: Using this value of B , calculate the maximum allowable pressure by the following equation:

$$P_a = \left[\frac{2.167}{D_o/T} - 0.0833 \right] B$$

Step 4: If P_a is less than the external Design Pressure P , repeat the procedure using a larger value for T .

NC-3243 Spherical Shells

The minimum thickness of a spherical shell under external pressure shall be determined by the procedure given in NC-3133.4.

NC-3244 Stiffening Rings for Cylindrical Shells

NC-3244.1 Required Moment of Inertia for Circumferential Stiffening Rings.

The required moment of inertia of the combined ring shell section is given by the equation:

$$I_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{10.9}$$

The moment of inertia for a stiffening ring shall be determined by the procedure given in Step 1 through Step 6 below.

Step 1: Assuming that the shell has been designed and $D_o L_s$, and T are known, select a member to be used for the

10 When axial compressive loadings occur in addition to the external pressure, the combined axial loading shall meet the requirements of NC-3245.

stiffening ring and determine its area A_s and the value of I_s . Calculate B by the equation:

$$B = \left[\frac{PD_o}{T + A_s / L_s} \right] \frac{3}{4}$$

Step 2: Enter the right hand side of the chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined in Step 1.

Step 3: Move horizontally to the material line for the Design Temperature.

Step 4: From this intersection move vertically to the bottom of the chart and read the value of A .

Step 5: Compute the value of the required moment of inertia I_s from the formula given above.

Step 6: If the required I_s is greater than the computed moment of inertia for the combined ring shell section selected in Step 1, a new section with a larger moment of inertia must be selected and a new I_s determined. If the required I_s is less than the computed moment of inertia for the section selected in Step 1, that section should be satisfactory.

NC-3244.2 Permissible Methods of Attaching Stiffening Rings.

Stiffening rings shall be attached to either the outside or the inside of the vessel in accordance with NC-4267.

NC-3245 Cylinders Under Axial Compression

The maximum allowable compressive stress in cylindrical shells subjected to loadings that produce longitudinal compressive stresses shall be the smaller of the values determined by (a) and (b) below:

(a) the S_m value for the applicable material at Design Temperature given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1;

(b) the value of the factor B determined in accordance with NC-3133.6(b).

NC-3250 WELDED JOINTS

NC-3251 Welded Joint Categories

Welded joint categories are defined in NC-3351.

NC-3252 Permissible Types of Welded Joints

The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle α not exceeding 30 deg. are considered as meeting the requirements for butt joints. Fig. NC-3352-1 shows typical butt welds for each category joint.

NC-3252.1 Joints of Category A.

All welded joints of Category A shall meet the fabrication requirements of NC-4263 and shall be capable of being examined in accordance with NC-5251.

NC-3252.2 Joints of Category B.

All welded joints of Category B shall meet the fabrication requirements of NC-4264 and shall be capable of being examined in accordance with NC-5252. When fatigue analysis of Type 2 joints is required and backing strips are not removed, stress concentration factors of 2.0 for membrane stresses and of 2.5 for bending stresses shall be applied in the design of the joints.

NC-3252.3 Joints of Category C.

All welded joints of Category C shall meet the fabrication requirements of NC-4265 and shall be capable of being examined in accordance with NC-5253. Minimum dimensions shall be as specified in NC-3258.3 and NC-3258.4.

NC-3252.4 Joints of Category D.

All welded joints of Category D shall be in accordance with the requirements of NC-3359 and one of (a) through (d) below.

(a) *Butt Welded Nozzles.* Nozzles shall meet the fabrication requirements of NC-4266(a) and shall be capable of being examined in accordance with NC-5254. The minimum dimensions and geometrical requirements of Fig. NC-4266(a)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum

(b) *Full Penetration Corner Welded Nozzles.* Nozzles shall meet the fabrication requirements of NC-4266(b) and shall be capable of being examined as required in NC-5254. The minimum dimensions of Fig. NC-4266(b)-1 shall be met where:

t	= thickness of part penetrated, in.
t_n	= thickness of penetrating part, in.

Page 94

t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum
r_3	= $\frac{1}{4}t_n$ or $\frac{3}{8}$ in. (10 mm), whichever is less, or chamfer at 45 deg. to at least $\frac{5}{16}$ in. (8 mm).

(c) *Pad and Screwed Fitting Types of Welded Nozzles.* Nozzles and fittings shall meet the fabrication requirements of NC-4266(c) and shall be capable of being examined in accordance with NC-5254. The minimum dimensions and geometrical requirements of Fig. NC-4266(c)-1 shall be met, where:

t_e	= thickness of reinforcement element, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less

t_n	= nominal thickness of neck, in.
t	= nominal thickness of shell, in.
r_1	= $\frac{1}{4}t_n$ or $\frac{3}{8}$ in., whichever is less
r_3	= $\frac{1}{4}t_g$ or $\frac{3}{8}$ in., whichever is less, or chamfer at 45 deg. to at least $\frac{5}{16}$ in.
c	= smaller of $0.7t_e$ or $0.7t$

(d) *Attachment of Nozzles Using Partial Penetration Welds.* Partial penetration welds shall meet the fabrication requirements of NC-4266(d) and shall be capable of being examined in accordance with NC-5254. They shall be used only for attachments such as instrumentation openings and inspection openings, which are subjected to essentially no external mechanical loadings and on which there will be no thermal stresses greater than in the vessel itself. Such attachments shall satisfy the rules for reinforcement of openings, except that no material in the neck shall be used for reinforcement in the attachment. The inside diameter of such openings shall not exceed 4 in. The minimum dimensions of Fig. NC-4266(d)-1 shall be met where:

t_n	= nominal thickness of neck, in.
t	= nominal thickness of vessel, in.
t_w	= depth of weld penetration, not less than $1\frac{1}{4}t_n$ in.
t_c	= $0.7t$ or $\frac{1}{4}$ in., whichever is less
r_1	= $\frac{1}{4}t_n$ or $\frac{3}{4}$ in., whichever is less
d	= outside diameter of nozzle, in.
C	= maximum diametral clearance between nozzle and vessel penetration, in.
	= 0.010 for $d \leq 1$ in.
	= 0.020 for 1 in. $< d \leq 4$ in.
	= 0.030 for $d > 4$ in., except that the above limits on maximum clearance need not be met for the full length of the opening, provided there is a region at the weld preparation and a region near the end of the opening opposite the weld which does meet the above limit on maximum clearance and the latter region is extensive enough (not necessarily continuous) to provide a positive stop for nozzle deflection

NC-3254 Structural Attachment Welds

Welds for structural attachments shall meet the requirements of NC-4267.

NC-3255 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and complete joint penetration, except as otherwise permitted in NC-3252.4.

NC-3257 Welded Joints Subject to Bending Stress

The requirements of NC-3357 shall be met.

NC-3258 Design Requirements for Head Attachments

NC-3258.1 Skirt Length of Formed Heads

(a) Ellipsoidal and other types of formed heads, concave or convex to the pressure, shall have a skirt length not less than that shown in Fig. NC-3358-1.

(b) A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections as shown in Fig. NC-3358-1 shall be provided at joints between formed heads and shells that differ in thickness by more than one-fourth the thickness of the thinner section or by more than $\frac{1}{8}$ in., whichever is less. When a taper is required on any formed head thicker than the shell and intended for butt welded attachment (Fig. NC-3358-1), the skirt shall be long enough so that the required length of taper does not extend beyond the tangent line.

NC-3258.2 Unstayed Flat Head Welded to Shells.

The requirements of welded unstayed flat heads to shells are given in NC-3225, NC-3258.3, and NC-3258.4.

NC-3258.3 Head Attachments Using Corner Joints.

When shells, heads, or other pressure parts are welded to a forged or rolled plate to form a corner joint, the welds shall meet the requirements given in (a) through (e) below.

(a) On the cross section through the welded joint, the line between the weld metal and the forged or rolled plate being attached shall be projected on planes both parallel to and perpendicular to the surface of the plate being attached, in order to determine the dimensions a and b , respectively.

(b) For flange rings of bolted flanged connections and for flat heads and supported and unsupported tube

Page 95

sheets with a projection for a bolted connection, the sum of a and b shall be not less than three times the nominal wall thickness of the abutting pressure parts.

(c) For other parts, the sum of a and b shall be not less than two times the nominal wall thickness of the abutting pressure parts. Examples of such parts are flat heads and supported and unsupported tubesheets without a projection for a bolted connection and the side plates of a rectangular vessel.

(d) Joint details that have a dimension through the joint less than the thickness of the shell, head, or other pressure part or that provide eccentric attachment are not permitted.

(e) The minimum dimensions in Figs. NC-4265-1 and NC-4265-2 are as follows:

(1) Fig. NC-4265-1

Sketch (a)

$a + b$ not less than $2t_s$

$b + c$ not less than t_s

t_p not less than t_s

Sketch (b)

$a + b$ not less than $2t_s$

Sketch (c)

$a + b$ not less than $3t_s$

$b + c$ not less than t_s

Sketches (d) and (e)

(a) For forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle not greater than 45 deg. measured from the face:

$c = 0.7t_s$ or $\frac{1}{4}$ in., whichever is less

b = the lesser of $t_s/2$ or $T/4$
 T, t_s = nominal thickness of welded parts

(b) For all other material forms and for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle greater than 45 deg. measured from the face:

c = $0.7t_s$ or $1/4$ in., whichever is less
 b = the lesser of t_s or $T/2$
 T, t_s = nominal thickness of welded parts sketches (f) and (g)
 c = $0.7t_s$ or $1/4$ in., whichever is less

(2) Fig. NC-4265-2

Sketch (a)

(a) For forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle not greater than 45 deg. measured from the face:

t_c = $0.7t_n$ or $1/4$ in., whichever is less
 t_w = the lesser of $t_n/2$ or $t/4$
 t, t_n = nominal thickness of welded parts, in.

(b) For all other material forms and for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle greater than 45 deg. measured from the face:

t_c = $0.7t_n$ or $1/4$ in., whichever is less
 t_w = the lesser of t_n or $t/2$
 t, t_n = nominal thicknesses of welded parts, in.

Sketch (b)

t and t_n = nominal thickness of welded parts, in.
 h or g_1 = $0.25t_n$ but not less than $1/4$ in.

Sketch (c)

t_n = nominal thickness of neck, in.

$a + b$ not less than $3t_n$

c not less than t_n

NC-3258.4 Head Attachments Using Butt Welds.

When flat heads are attached using butt welds, as shown in Fig. NC-4243.1-1, the minimum dimensions are as follows:

(a) Sketch (a)

r not less than $1.5t_s$

(b) Sketch (b)

r not less than $1.5t_s$

e not less than t_s

- (c) *Sketch (c)*
 h not less than $1.5t_s$
- (d) *Sketch (d)*
 t_f not less than $2t_s$
 r not less than $3t_f$
- (e) *Sketch (e)*
 t_f not less than $2t_s$
 r not less than $3t_f$
 e not less than t_f

NC-3259 Design Requirements for Nozzle Attachment Welds and Other Connections

The minimum design requirements for nozzle attachment welds and other connections are set forth in (a) through (c) below.

(a) *Permitted Types of Nozzles and Other Connections.* Nozzles and other connections may be any of the types for which rules are given in this Subarticle, provided the requirements of (1) through (7) below are met.

- (1) Nozzles shall meet requirements regarding location.
- (2) The attachment weld shall meet the requirements of NC-3252.4.
- (3) The requirements of NC-3230 shall be met.
- (4) Type No. 1 full penetration joints shall be used when the openings are in shells $2\frac{1}{2}$ in. (64 mm) or more in thickness.
- (5) The welded joints shall be examined by the methods stipulated in NC-5250.

Page 96

- (6) Studded connections shall meet the requirements of NC-3262.4.
- (7) Threaded connections shall meet the requirements of NC-3270.

(b) *Provision of Telltale Holes for Air Testing.* Reinforcing plates and saddles attached to the outside of a vessel shall be provided with at least one telltale hole, of maximum size $\frac{1}{4}$ in. pipe tap, that may be tapped for a preliminary compressed air and soap solution or equivalent test for tightness of welds that seal off the inside of the vessel. These telltale holes may be left open or may be plugged when the vessel is in service. If the holes are plugged, the plugging material used shall not be capable of sustaining pressure between the reinforcing plate and the vessel wall. Telltale holes shall not be plugged during heat treatment.

(c) *Attachments.* Typical attachments are shown in Fig. NC-4267-1. The minimum dimensions in this figure are as follows:

$$a \geq t/4; b \geq t/2; C \geq t$$

t	= thickness of attached member, in.
c	= minimum thickness of weld metal from the root to the face of the weld, in.

NC-3260 SPECIAL VESSEL REQUIREMENTS

NC-3261 Transition Joints Between Sections of Unequal Thickness

Unless the requirements of Appendix XIII, XIV, or II are shown to be satisfied, a tapered transition as shown in Figs.

NC-3358-1 and NC-3361-1 shall be provided at joints of Categories A and B between sections that differ in thickness by more than one-fourth of the thickness of the thinner section or by more than $\frac{1}{8}$ in. The transition may be formed by any process that will provide a uniform taper. The weld may be partly or entirely in the tapered section. When Appendix XIII, XIV, or II are not used, the following requirements of (a) through (e) below shall also apply.

(a) The length of taper shall be not less than three times the offset between adjacent surfaces.

(b) Figure NC-3361-1 shall apply to all joints of categories A and B except joints connecting formed heads to main shells, for which case Fig. NC-3358-1 shall apply.

(c) When a taper is required on any formed head intended for butt welded attachment, the skirt shall be long enough so that the required length of taper does not extend beyond the tangent line.

(d) An ellipsoidal or hemispherical head which has a greater thickness than a cylinder of the same inside diameter may be machined to the outside diameter of the cylinder, provided the remaining thickness is at least as great as that required for a shell of the same diameter.

(e) The requirements of this paragraph are not applicable to flange hubs.

NC-3262 Bolted Flanged Connections

NC-3262.1 Flanges and Flanged Fittings Conforming to ANSI B16.5.

Except as provided in NC-3262.3, the dimensional requirements of flanges used in bolted flange connections to external piping shall conform to ANSI B16.5, Steel Pipe Flanges and Flanged Fittings. Flanges and flanged fittings conforming to ANSI B16.5 and listed in Tables 13 through 33 of that Standard, with the exception of threaded and socket welding types, may be used at the pressure-temperature ratings specified in that Standard. Flanges within the size and pressure range of ANSI B16.5, Tables 13 through 33, may be designed by interpolation.

NC-3262.2 Slip-On Flanges Conforming to ANSI B16.5.

Slip-on flanges conforming to ANSI B16.5 may be used, provided all the conditions of (a) through (e) below are met.

(a) The specified minimum tensile strengths of materials do not exceed 80.0 ksi (552 MPa).

(b) The minimum elongation of materials is 12% in 2 in. (51 mm).

(c) The thickness of the materials to which the flange is welded does not exceed $1\frac{1}{4}$ in. (32 mm).

(d) The throat thickness, taken as the minimum thickness in any direction through the attaching fillet welds, is at least 0.7 times the thickness of the material to which the flange is welded.

(e) The fatigue analysis required for nozzles with separate reinforcement and nonintegral attachments, as set forth in NC-3219.3, is applied to the design.

NC-3262.3 Flanges Not Conforming to ANSI B16.5.

Flanges which do not conform to ANSI B16.5 shall be designed in accordance with the Rules for Bolted Flange Connections, Appendix XI, or by the rules of Appendices II, XIII, and XIV.

NC-3262.4 Studded Connections.

Where tapped holes are provided for studs, the threads shall be full and clean and shall engage the stud for a length not less than the larger of d or

$$(0.75d_s) \times \frac{\text{Design stress intensity value of stud material at Design Temperature}}{\text{Design stress intensity value of tapped material at Design Temperature}}$$

in which d is the root diameter of the stud, except that the thread engagement need not exceed $1\frac{1}{2}d_s$.

NC-3263 Access and Inspection Openings

The requirements for access and inspection openings are given in NC-3363.

NC-3264 Attachments and Supports

NC-3264.1 General Requirements.

Supports, lugs, brackets, stiffeners, and other attachments may be welded or stud bolted to detailed fatigue analysis in accordance with the requirements of Appendices XIII and XIV unless the conditions of NC-3219 are met. Attachments shall conform reasonably to the curvature of the shell to which they are to be attached. The fabrication requirements of NC-4267 and the examination requirements of NC-5250 shall be met.

NC-3264.2 Attachment Materials.

Materials welded directly to pressure parts shall meet the requirements of NC-2190.

NC-3264.3 Design of Attachments.

The effects of attachments, including external and internal piping connections, shall be taken into account in the design. Attachments shall meet the requirements of NC-3135.

NC-3264.4 Design of Supports

(a) All vessels shall be so supported and the supporting members so arranged and attached to the vessel as to provide for the maximum imposed loadings. Wind and earthquake loads need not be assumed to occur simultaneously.

(b) All supports should be designed to prevent excessive localized stresses due to temperature changes in the vessel or deformations produced by the internal pressure.

(c) Horizontal vessels supported by saddles shall provide bearing extending over at least one-third of the shell circumference.

(d) Additional requirements for the design of supports are given in NCA-3240 and Subsection NF.

NC-3264.5 Types of Attachment Welds.

Welds attaching nonpressure parts or stiffeners to pressure parts shall meet the requirements of NC-4267.

NC-3264.6 Stress Values for Weld Material.

Attachment weld strength shall be based on the nominal weld area and the design stress intensity values in Tables 2A,

2B, and 4, Section II, Part D, Subpart 1 and stress criteria in NC-3200 for the weaker of the two materials joined, or, where weaker weld metal is permitted, the design stress intensity values of the weld metal multiplied by the following reduction factors: 0.5 for fillet welds NC-3264.5; 0.75 for partial penetration groove or partial penetration groove plus fillet welds NC-3264.5; 1.0 for complete weld penetration. The nominal weld area for fillet welds is the throat area; for groove welds, the depth of penetration times the length of weld; and for groove welds with fillet welds, the combined throat and depth of penetration, exclusive of reinforcement, times the length of weld.

(a) *Attachment Welds - Evaluation of Need for Fatigue Analysis.* In applying Condition AP or BP of NC-3219.3, fillet welds and partial penetration welds are considered nonintegral attachments, except that the following welds need not be considered:

(1) welds for minor attachments

(2) welds for supports which may be considered integral as covered by Conditions A and B of NC-3219.2

NC-3266 Threaded Connections

(a) Threads

(1) Pipes, tubes, and other threaded connections that conform to the ANSI B2.1, Standard for Pipe Threads, may be screwed into a threaded hole in a vessel wall, provided the pipe engages the minimum number of threads specified in Table NC-3266-1 after allowance has been made for curvature of the vessel wall. A built-up pad or a properly attached plate or fitting shall be used to provide the metal thickness and number of threads required in Table NC-3266-1 or to furnish reinforcement when required.

(2) Straight threaded connections may be employed as provided for in NC-3266(b)(2).

(b) Restrictions on the Use of Threaded Connections

(1) *Taper Threaded Connections.* Internal taper pipe thread connections larger than 2 in. (51 mm) shall not be used.

(2) Straight Threaded Connections

(a) Threaded connections employing straight threads shall provide for mechanical seating of the assembly by a shoulder or similar means. Straight thread center openings in vessel heads shall meet the requirements of NC-3230. The length of the thread shall be calculated for the opening design and they shall not exceed the smaller of one-half the vessel

Page 98

diameter or 8 in. nominal pipe size. In addition, they shall be placed at a point where the calculated stress without a hole, due to any combination of design pressure and mechanical loadings expected to occur simultaneously, is not more than $0.5S_m$.

**TABLE NC-3266-1
MINIMUM NUMBER OF PIPE THREADS
FOR CONNECTIONS**

Size of Pipe Connection, in.	Threads Engaged	Min. Plate Thickness Required, in.
$\frac{1}{2}$	6	0.43
$\frac{3}{4}$	6	0.43
1	6	0.61
$1\frac{1}{4}$	6	0.61
$1\frac{1}{2}$	6	0.61
2	8	0.70

TABLE NC-3266-1 MINIMUM NUMBER OF PIPE THREADS FOR CONNECTIONS

(b) Threaded connections above $2\frac{3}{4}$ in. (70 mm) in diameter may be used only if they meet the requirements of NC-3219, or, if these requirements are not met, a detailed fatigue analysis shall be made in accordance with the rules of Appendices XIII and XIV.

NC-3300 VESSEL DESIGN

NC-3310 GENERAL REQUIREMENTS

Class 2 vessel requirements as stipulated in the Design Specifications (NCA-3250) shall conform to the design requirements of this Article.

NC-3320 DESIGN CONSIDERATIONS

NC-3321 Stress Limits for Design and Service Loadings

Stress¹¹ limits for Design and Service Loadings are specified in Table NC-3321-1. The symbols used in Table NC-3321-1 are defined as follows:

σ_m	= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, psi. This stress is the same as σ_m .

except that it includes the effect of discontinuities.

11 Stress means the maximum normal stress.

σ_b

= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.

S

= allowable stress value given in Table 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the condition under consideration.

**TABLE NC-3321-1
STRESS LIMITS FOR DESIGN AND SERVICE
LOADINGS¹**

Service Limit	Stress Limits [Note (2)]
Design and Level A	$\sigma_m \leq 1.0 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5 S$
Level B	$\sigma_m \leq 1.10 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65 S$
Level C	$\sigma_m \leq 1.5 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8 S$
Level D	$\sigma_m \leq 2.0 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4 S$

NOTES:

(1) See NC-3321.1 for definitions of symbols.

(2) These limits do not take into account either local or general buckling which might occur in thin-wall vessels.

TABLE NC-3321-1 STRESS LIMITS FOR DESIGN AND SERVICE LOADINGS¹

Typical examples of locations for which σ_m , σ_L , σ_b are applicable are shown in Table NC-3321-2.

NC-3322 Special Considerations

The provisions of NC-3120 apply.

NC-3323 General Design Rules

The provisions of NC-3130 apply except as modified by the rules of this Subarticle. In case of conflict, this Subarticle governs the design of vessels.

NC-3324 Vessels Under Internal Pressure

NC-3324.1 General Requirements.

Equations are given for determining the minimum thicknesses under internal pressure loading in cylindrical and spherical shells and ellipsoidal, torispherical, toriconical, conical, and hemispherical heads. Provision shall be made for

Page 99

any of the other loadings listed in NC-3111 when such loadings are specified. Pages 100-100

TABLE NC-3321-2
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	σ_m Q
		Axial thermal gradient	Membrane Bending	Q Q
	Junction with head or flange	Internal pressure	Membrane Bending	σ_L Q [Note (2)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section; stress component perpendicular to cross section.	σ_m
		External load or moment	Bending across full section; stress component perpendicular to cross section.	σ_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	σ_L Q F
	Any location	Temperature difference between shell and head	Membrane Bending	Q Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	σ_m σ_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	σ_L [Note (3)] Q
Flat head	Center region	Internal pressure	Membrane Bending	σ_m σ_b
	Junction to shell	Internal pressure	Membrane Bending	σ_L Q [Note (2)]
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (averaged through cross section) Bending (averaged through width of ligament, but gradient through plate) Peak	σ_m σ_b F
	Isolated or atypical ligament	Pressure	Membrane Bending Peak	Q F F

Table continues on next page

TABLE NC-3321-2 (CONT'D)
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Nozzle	Within the limits of reinforcement defined by NC-3334	Pressure and external loads and moments, including those attributable to restrained free end displacements of attached piping	General membrane Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	σ_m σ_m
		Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of attached piping	General membrane stresses	σ_m
	Outside the limits of reinforcement defined by NC-3334	Pressure and external loads and moments other than those attributable to restrained free end displacements of the attached piping	Membrane Bending	σ_L σ_b
		Pressure and all external loads and moments	Membrane Bending Peak	σ_L Q F
	Nozzle wall	Gross structural discontinuities	Local membrane Bending Peak	σ_L Q F
		Differential expansion	Membrane Bending Peak	Q Q F
Cladding	Any	Differential expansion	Membrane Bending	F F
Any	Any	Radial temperature distribution [Note (4)]	Equivalent linear stress [Note (5)]	Q
			Nonlinear portion of stress distribution	F
Any	Any	Any	Stress concentration (notch effect)	F

NOTES:

- (1) Q and F classifications of stresses refers to other than Design Condition.
- (2) If the bending moment at the edge is required to maintain the bending stress in the middle within acceptable limits, the edge bending is classified as σ_b . Otherwise, it is classified as Q .
- (3) Consideration must also be given to the possibility of wrinkling and excessive deformation in vessels with large diameter-to-thickness ratio.
- (4) Consider possibility of thermal stress ratchet.
- (5) *Equivalent linear stress* is defined as the linear distribution which has the same net bending moment as the actual stress distribution.

TABLE NC-3321-2 (CONT'D) CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

FIG. NC-3324.2-1 PRINCIPAL DIMENSIONS OF TYPICAL HEADS

FIG. NC-3324.2-1 PRINCIPAL DIMENSIONS OF TYPICAL HEADS

NC-3324.2 Nomenclature.

The symbols used in this paragraph and Fig. NC-3324.2-1 are defined as follows:

t	= minimum required thickness of shell or head after forming, exclusive of corrosion allowance, in.
P	= Design Pressure, psi
R	= inside radius of the shell course under consideration before corrosion allowance is added, in.
R_o	= outside radius of the shell course under consideration, in.
S	= maximum allowable stress value, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)
D	= inside diameter of the head skirt; or inside length of the major axis of an ellipsoidal head; or inside diameter of a conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_o	= outside diameter of the head skirt; or outside length of the major axis of an ellipsoidal head; or outside diameter of a

	conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_I	= inside diameter of the conical portion of a toriconical head at its point of tangency to the knuckle, measured perpendicular to the axis of the cone, in.
L	= inside spherical or crown radius for torispherical and hemispherical heads, in.
L	= $K_1 D$ for ellipsoidal heads in which K_1 is obtained from Table NC-3332.2-1, in.
L_o	= outside spherical or crown radius, in.
r	= inside knuckle radius, in.
h	= one-half of the length of the minor axis of the ellipsoidal head or the inside depth of the ellipsoidal head measured from the tangent line, head bend line, in.
K	= a factor in the formulas for ellipsoidal heads depending on the head proportion, $D/2h$ (Table NC-3324.2-1)
$D/2h$	= ratio of the major to the minor axis of ellipsoidal heads, which equals the inside diameter of the skirt of the head divided by twice the inside height of the head and is used in Table NC-3324.2-1

Page 102

α	= one-half of the included apex angle of the cone at the centerline of the head
----------	---

TABLE NC-3324.2-1
VALUES OF FACTOR K
 Use Nearest Value of $D/2h$; Interpolation Unnecessary

$D/2h$	3.0	2.9	2.8	2.7	2.6	2.5	2.4	2.3	2.2	2.1	2.0

TABLE NC-3324.2-1 VALUES OF FACTOR K

NC-3324.3 Cylindrical Shells.

The minimum thickness of cylindrical shells shall be the greater thickness as given by (a) through (d) below.

(a) *Circumferential Stress (Longitudinal Joints)*. When the thickness does not exceed one-half of the inside radius, or P does not exceed 0.385 S , the following equations shall apply:

$$t = \frac{PR}{S - 0.6P} \quad \text{or} \quad P = \frac{St}{R + 0.6t}$$

(b) *Longitudinal Stress (Circumferential Joints)*. When the thickness does not exceed one-half of the inside radius, or P does not exceed $1.25S$, the following equations shall apply:

$$t = \frac{PR}{2S + 0.4P} \quad \text{or} \quad P = \frac{2St}{R - 0.4t}$$

(c) *Thickness of Cylindrical Shells*. The following formulas, in terms of the outside radius, are equivalent to and may be used instead of those given in (a) above:

$$t = \frac{PR_o}{S + 0.4P} \quad \text{or} \quad P = \frac{St}{R_o - 0.4t}$$

(d) *Thick Cylindrical Shells*

(1) *Circumferential Stress (Longitudinal Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius, or when P exceeds $0.385S$, the following equations shall apply.

When P is known and t is desired:

$$t = R (Z^{1/2} - 1) = R_o \frac{(Z^{1/2} - 1)}{Z^{1/2}}$$

where

$$Z = \frac{S + P}{S - P}$$

When t is known and P is desired:

$$P = S \left(\frac{Z - 1}{Z + 1} \right)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

(2) *Longitudinal Stress (Circumferential Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius, or when P exceeds 1.25S, the following equations shall apply.

When P is known and t is desired:

$$t = R (Z^{1/2} - 1) = R_o \frac{(Z^{1/2} - 1)}{Z^{1/2}}$$

where

$$Z = \left(\frac{P}{S} + 1 \right)$$

When t is known and P is desired:

$$P = S(Z - 1)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

NC-3324.4 Spherical Shells

(a) When the thickness of the shell of a spherical vessel does not exceed $0.356R$, or P does not exceed $0.665S$, the following equations shall apply. Any reduction

Page 103

in thickness within a shell course of a spherical shell shall be in accordance with NC-3361.

$$t = \frac{PR}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{R + 0.2t}$$

(b) The following equations, in terms of the outside radius, are equivalent to and may be used instead of those given in (a) above.

$$t = \frac{PR_o}{2S + 0.8P}$$

$$P = \frac{2St}{R_o - 0.8t}$$

(c) When the thickness of the shell of a spherical vessel or of a hemispherical head under internal pressure exceeds $0.356R$, or when P exceeds $0.665S$, the following equations shall apply.

When P is known and t is desired:

$$t = R (Y^{1/3} - 1) = R_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(S + P)}{2S - P}$$

When t is known and P is desired:

$$P = 2S \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{R + t}{R} \right)^3 = \left(\frac{R_o}{R_o - t} \right)^3$$

NC-3324.5 Formed Heads, General Requirements.

Formed heads shall meet the requirements of (a) through (g) below.

(a) All formed heads, thicker than the shell and concave to pressure, for butt welded attachment, shall have a skirt length sufficient to meet the requirements of Fig. NC-3358.1(a)-1 when a tapered transition is required.

(b) Any taper at a welded joint within a formed head shall be in accordance with NC-3361. The taper at a circumferential welded joint connecting a formed head to a main shell shall meet the requirements of NC-3358 for the respective type of joint shown therein.

(c) All formed heads concave to pressure and for butt welded attachment need not have an integral skirt when the thickness of the head is equal to or less than the thickness of the shell. When a skirt is provided, its thickness shall be at least that required for a seamless shell of the same diameter.

(d) The inside crown radius to which an unstayed head is dished shall be not greater than the outside diameter of the skirt of the head. The inside knuckle radius of a torispherical head shall be not less than 6% of the outside diameter of the skirt of the head but in no case less than three times the head thickness.

(e) When an ellipsoidal, torispherical, hemispherical, conical, or toriconical head is of a lesser thickness than required by the rules of this paragraph, it shall be stayed as a flat surface according to the rules of NC-3329.

(f) If a torispherical, ellipsoidal, or hemispherical head is formed with a flattened spot or surface, the diameter of the flat spot shall not exceed that permitted for flat heads as given by Eq. (1) or (2) of NC-3325.2 using $C = 0.25$.

(g) Openings in formed heads under internal pressure shall comply with the requirements of NC-3330.

NC-3324.6 Ellipsoidal Heads

(a) *Ellipsoidal Heads.* The required thickness of a dished head of semiellipsoidal form, in which one-half the minor axis, inside depth of the head minus the skirt, equals one-fourth the inside diameter of the head skirt, shall be determined by:

$$t = \frac{PD}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{D + 0.2t}$$

(b) *Ellipsoidal Heads of Other Ratios.* The minimum required thickness of an ellipsoidal head of other than a 2:1 ratio shall be determined by:

$$t = \frac{PDK}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{KD + 0.2t}$$

$$t = \frac{PD_o K}{2S + 2P(K - 0.1)}$$

$$P = \frac{2St}{KD_o - 2t(K - 0.1)}$$

where

$$K = \frac{1}{6} \left[2 + \left(\frac{D}{2h} \right)^2 \right]$$

Numerical values of the factor K are given in Table NC-3324.2-1.

NC-3324.7 Hemispherical Heads

(a) When the thickness of a hemispherical head does not exceed $0.356L$ or P does not exceed $0.665S$, the following equations shall apply:

$$t = \frac{PL}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{L + 0.2t}$$

(b) When the thickness of the hemispherical head under internal pressure exceeds $0.356L$, or when P exceeds $0.665S$, the following equations shall apply:

$$t = L (Y^{1/3} - 1) = L_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(S + P)}{2S - P}$$

or

$$P = 2S \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{L + t}{L} \right)^3 = \left(\frac{L_o}{L_o - t} \right)^3$$

NC-3324.8 Torispherical Heads

(a) *Torispherical Heads With a 6% Knuckle Radius.* The required thickness of a torispherical head in which the knuckle radius is 6% of the inside crown radius shall be determined by:

$$t = \frac{0.885PL}{S - 0.1P} \quad \text{or} \quad P = \frac{St}{0.885L + 0.1t}$$

(b) *Torispherical Heads of Other Proportions.* The required thickness of a torispherical head in which the knuckle radius is other than 6% of the crown radius shall be determined by:

$$t = \frac{PLM}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{LM + 0.2t}$$

$$t = \frac{PL_oM}{2S + P(M - 0.2)}$$

or

$$P = \frac{2St}{ML_o - t(M - 0.2)}$$

where

$$M = \frac{1}{4} \left(3 + \sqrt{\frac{L}{r}} \right)$$

Numerical values of the factor M are given in Table NC-3324.8(b)-1.

(c) Torispherical heads made of materials having a specified minimum tensile strength exceeding 80 ksi shall be designed using a value of S equal to 20 ksi at room temperature and reduced in proportion to the reduction in maximum allowable stress values at temperature for the material as shown in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

NC-3324.9 Conical Heads Without Transition Knuckle.

The required thickness of conical heads or conical shell sections that have a half apex angle α not greater than 30 deg. shall be determined by:

$$t = \frac{PD}{2 \cos \alpha (S - 0.6P)} \quad \text{or} \quad P = \frac{2St \cos \alpha}{D + 1.2t \cos \alpha}$$

For α greater than 30 deg., see NC-3324.11(b)(5). A compression ring shall be provided when required by the rule in NC-3324.11(b).

NC-3324.10 Toriconical Heads.

Toriconical heads in which the inside knuckle radius is neither less than 6% of the outside diameter of the head skirt nor less than three times the knuckle thickness shall be used

Page 105

when the angle α exceeds 30 deg., except when the design complies with NC-3324.11. The required thickness of the knuckle shall be determined by the first equation of NC-3324.8(b) in which

$$L = \frac{D_1}{2 \cos \alpha}$$

TABLE NC-3324.8(b)-1
VALUES OF FACTOR M
Use Nearest Value of L/r ; Interpolation Unnecessary

L/r	1.0	1.25	1.50	1.75	2.00	2.25	2.50	2.75	3.00	3.25	3.50

M	1.52	1.54	1.56	1.58	1.60	1.62	1.65	1.69	1.72	1.75	1.77

NOTE:

(1) Maximum ratio allowed by NC-3324.5(d) when L equals the outside diameter of the skirt of the head.

TABLE NC-3324.8(b)-1

The required thickness of the conical portion shall be determined by the equation in NC-3324.9, using D_1 in place of D .

NC-3324.11 Reducer Sections

(a) General Requirements

(1) The rules of NC-3324.11(a) apply to concentric reducer sections.

(2) The symbols used are defined as follows:

D_1	= inside diameter of reducer section at point of tangency to the knuckle or reverse curve, in.
A	= required area of reinforcement, sq in.
A_e	= effective area of reinforcement, due to excess metal thickness, sq in.
Δ	= value to indicate need for reinforcement at cone-to-cylinder intersection having a half-apex angle $\alpha \leq 30$ deg. When $\Delta \geq \alpha$, no reinforcement at the junction is required [Tables NC-3324.11(b)(2)-1 and NC-3324.11(b)(3)-1].
m	= the lesser of

$$\left[\frac{t_s}{t} \cos (\alpha - \Delta) \right] \text{ or}$$

$$\left[\frac{t_c \cos \alpha \cos (\alpha - \Delta)}{t} \right]$$

R_L	= inside radius of larger cylinder, in.
R_s	= inside radius of smaller cylinder, in.

**TABLE NC-3324.11(b)(2)-1

NOTE:

(1) $\Delta = 30$ deg. for greater values of *P/S*.

TABLE NC-3324.11(b)(3)-1 VALUES OF Δ FOR JUNCTIONS AT THE SMALL CYLINDER FOR $\alpha \leq 30$ DEG.

(3) The thickness of each element of a reducer, as defined in (4) below, under internal pressure shall not be less than that computed by the applicable equation. In addition, provisions shall be made for any of the other loadings listed in NC-3111 when such loadings are expected.

(4) A transition section reducer consisting of one or more elements may be used to join two cylindrical shell sections of different diameters but with a common axis, provided the requirements of (a) and (b) below are met.

(a) *Conical Shell Section.* The required thickness of a conical shell section or the allowable pressure for such a section of given thickness shall be determined by the equations given in NC-3324.9.

(b) *Knuckle Tangent to the Larger Cylinder.* Where a knuckle is used at the large end of a reducer section, its shape shall be that of a portion of an ellipsoidal, hemispherical, or torispherical head. The thickness and other dimensions shall satisfy the requirements.

(5) When elements of (4) above having different thicknesses are combined to form a reducer, the joints including the plate taper required by NC-3361 shall lie entirely within the limits of the thinner element being joined.

(6) A reducer may be a simple conical shell section [Fig. NC-3324.11(a)(6)-1 sketch (a)] without knuckle, provided the half apex angle, α , is not greater than 30 deg. except as provided for in (b) below. A reinforcement ring shall be provided at either or both ends of the reducer when required by (b) below.

(7) A toriconical reducer [Fig. NC-3324.11(a)(6)-1 sketch (b)] may be shaped as a portion of a toriconical shell, a portion of a hemispherical head plus a conical section, or a portion of an ellipsoidal head plus a conical section, provided the half apex angle, α , is not greater than 30 deg., except as provided for in (b) below. A reinforcement ring shall be provided at the small end of a conical reducer element when required by (b) below.

(8) Reverse curve reducers [Fig. NC- 3324.11(a)(6)-1 sketches (c) and (d)] may be shaped of elements other than those illustrated.

(b) Supplementary Requirements for Reducer Sections and Conical Heads Under Internal Pressure

(1) The equations of (2) and (3) below provide for the design of reinforcement, if needed, at the cone to cylinder junctions for reducer sections and conical heads where all the elements have a common axis and the half apex angle $\alpha \leq 30$ deg. In (5) below, provision is made for special analysis in the design of cone to cylinder intersections with or without reinforcing rings where α is greater than 30 deg.

(2) Reinforcement shall be provided at the junction of the cone with the large cylinder for conical heads and reducers without knuckles when the value of Δ , obtained from Table NC-3324.11(b)(2)-1, using the appropriate ratio P/S , is less than α . Interpolation may be made in the table.

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following equation:

$$A = \frac{PR_L^2}{2S} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha \quad (1)$$

(1)

(b) When the thickness, less corrosion allowance, of both the reducer and cylinder exceeds that required by the applicable design equations, the minimum excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following equation:

$$(2) A_e = 4t_e \sqrt{R_L t_s}$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_L t_s}$ from the junction of the reducer and the cylinder. The centroid of the added area shall be within a distance of $0.5\sqrt{R_L t_s}$ from the junction.

(3) Reinforcement shall be provided at the junction of the conical shell of a reducer without a flare and the small cylinder when the value of Δ obtained from Table NC-3324.11(b)(3)-1, using the appropriate ratio P/S , is less than α .

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following formula:

$$A = \frac{PR_s^2}{2S} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha \quad (3)$$

(3)

(b) When the thickness, less corrosion allowance, of either the reducer or cylinder exceeds that required by the applicable design equation, the excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following equation:

$$(4) A_e = m \sqrt{R_s t} [(t_c - (t/\cos \alpha) + (t_s - t)]$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of

Page 107

$\sqrt{R_s t}$ from the junction, and the centroid of the added area shall be within a distance of $0.5\sqrt{R_s t}$ from the junction.

GENERAL NOTES:

- (1) r_L shall not be less than the smaller of $0.12 (R_L + t)$ or $3t$.
- (2) r_s has no dimensional requirement.

FIG. 3324.11(a)(6)-1 LARGE HEAD OPENINGS, REVERSE CURVE, AND CONICAL SHELL REDUCER SECTIONS

FIG. 3324.11(a)(6)-1 LARGE HEAD OPENINGS, REVERSE CURVE, AND CONICAL SHELL REDUCER SECTIONS

(4) Reducers not described in NC-3324.11(a)(3), such as those made up of two or more conical frustums having different slopes, may be designed in accordance with (5) below.

(5) When the half apex angle α is greater than 30 deg., cone-to-cylinder junctions without a knuckle may be used, with or without reinforcing rings, if the design is based on stress analysis. When a stress analysis is made, the calculated localized stresses at the discontinuity shall not exceed the following values:

(a) membrane hoop stress plus average discontinuity hoop stress shall not be greater than $1.5S$;

(b) membrane longitudinal stress plus discontinuity longitudinal stress due to bending shall not be greater than $4S$, where the average discontinuity hoop stress is the average hoop stress across the wall thickness due to the discontinuity at the junction, disregarding the effect of Poisson's ratio times the longitudinal stress at the surfaces;

(c) the angle joint between the cone and cylinder shall be designed equivalent to a double butt welded joint and, because of the high bending stress, there shall be no weak zones around the angle joint. The thickness of the cylinder may have to be increased to limit the difference in thickness so that the angle joint has a smooth contour.

NC-3324.12 Nozzles

(a) The wall thickness of a nozzle or other connection shall not be less than the nominal thickness of the connecting piping. In addition, the wall thickness shall not be less than the thickness computed for the applicable loadings in NC-3111 plus the thickness added for corrosion. Except for access openings and openings for inspection only, the wall thickness shall not be less than the smaller of (1) and (2) below:

(1) the required thickness of the shell or head to which the connection is attached plus the corrosion allowance provided in the shell or head adjacent to the connection;

(2) the minimum thickness¹² of standard wall pipe plus the corrosion allowance on the connection; for nozzles larger than the largest pipe size included in ANSI B36.10, the wall thickness of that largest size, plus corrosion allowance.

12 The minimum thickness for all pipe materials is the nominal wall thickness listed in Table 2 of ANSI B36.10 less $12\frac{1}{2}\%$. For diameters other than those listed in the table, this shall be based on the next larger pipe size.

Page 108

(b) The allowable stress value for shear in a nozzle neck shall be 70% of the allowable tensile stress for the vessel material.

NC-3324.13 Nozzle Piping Transitions.

The stress limits of Table NC-3321-1 shall apply to all portions of nozzles which lie within the limits of reinforcement given in NC-3334, except as provided for in NC-3324.14. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of NC-3600.

NC-3324.14 Consideration of Standard Reinforcement

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of NC-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table NC-3321-1. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are specified, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table NC-3321-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case, the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit for σ_m in Table NC-3321-1 for a given condition.

NC-3324.15 Other Loadings.

When necessary, vessels shall be provided with stiffeners or other additional means of support to prevent overstress or large distortions under the external loadings listed in NC-3111 other than pressure and temperature.

NC-3325 Flat Heads and Covers

The minimum thickness of unstayed flat heads, cover plates, and blind flanges shall conform to the requirements given in this paragraph. These requirements apply to circular heads and covers. Some acceptable types of flat heads and covers are shown in Fig. NC-3325-1. In this figure, the dimensions of the component parts and the dimensions of the welds are exclusive of extra metal required for corrosion allowance.

NC-3325.1 Nomenclature.

The symbols used are defined as follows:

C	= a factor depending upon the method of attachment of head, shell dimensions, and other items as listed in NC-3325.3, dimensionless
d	= diameter, measured as indicated in Fig. NC-3325-1, in.
h_G	= gasket moment arm, equal to the radial distance from the centerline of the bolts to the line of the gasket reaction, as shown in Table XI-3221.1-2, in.
l	= length of flange of flanged heads, measured from the tangent line of knuckle, as indicated in Fig. NC-3325-1 sketch (a), in.

	(a), in.
m	= the ratio of t_f/t_s , dimensionless
P	= Design Pressure, psi
r	= inside corner radius on a head formed by flanging or forging, in.
S	= maximum allowable stress value, psi, from Tables 1A, 1B, and 3 Section II, Part D, Subpart 1 of Appendix I
t	= minimum required thickness of flat head or cover, exclusive of corrosion allowance, in.
t_f	= actual thickness of the flange on a forged head, at the large end, exclusive of corrosion allowance, as indicated in Fig. NC-3325-1 sketches (b-1) and (b-2), in.
t_h	= actual thickness of flat head or cover, exclusive of corrosion allowance, in.
t_r	= required thickness of shell, for pressure, in.
t_s	= actual thickness of shell, exclusive of corrosion allowance, in.
W	= total bolt load, lb, given for circular heads for Eqs. (3) and (4), XI-3223

NC-3325.2 Thickness.

The thickness of flat unstayed heads, covers, and blind flanges shall conform to one of the following two requirements.
13

(a) Circular blind flanges of ferrous materials conforming to ANSI B16.5 shall be acceptable for the diameters and pressure-temperature ratings in Tables 2 to 8 of that Standard, when of the types shown in Fig. NC-3325-1 sketches (d) and (e).

13 The formulas provide safe construction as far as stress is concerned. Greater thicknesses may be necessary if deflection would cause leakage at threaded or gasketed joints.

(b) The minimum required thickness of flat unstayed circular heads, covers, and blind flanges shall be calculated by the equation

$$(5) t = d \sqrt{CP/S}$$

except when the head, cover, or blind flange is attached by bolts causing an edge moment [Fig. NC-3325-1 sketches (d) and (e)], in which case the thickness shall be calculated by

$$(6) t = d \sqrt{CP/S + 1.27Wh_c/Sd^3}$$

FIG. NC-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

FIG. NC-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

When using Eq. (6), the thickness t shall be calculated for both service loadings and gasket seating, and the greater of the

two values shall be used. For service loadings, the value of P shall be the Design Pressure, and the values of S at the Design Temperature and W from Eq. (3) of XI-3223 shall be used. For gasket seating, P equals zero, and the values of S at atmospheric temperature and W from Eq. (4) of XI-3223 shall be used.

NC-3325.3 Values of C .

For the types of construction shown in Figs. NC-3325-1, NC-4243-1, NC-4243-2, and NC-4243.1-1, the minimum values of C to be used in Eqs. (5) and (6) shall be as given in (a) through (g) for Fig. NC-3325-1 and in (h) for Figs. NC-4243.1-1 and NC-4243-1, in (i) for Fig. NC-4243-2, and in (j) for Fig. NC-4243.1-1.

(a) In sketch (a), $C = 0.17$ for flanged circular heads forged integral with or butt welded to the vessel with an inside corner radius not less than three times the required head thickness, with no special requirement with regard to length of flange.

(1) $C = 0.10$ for circular heads, when the flange length for heads of the above design is not less than

$$l = \left(1.1 - 0.8 \frac{t_s^2}{t_h^2} \right) \sqrt{d t_h} \quad (7)$$

(7)

(2) $C = 0.10$ for circular heads, when the flange length l is less than the requirement in (1) above but the shell thickness is not less than

$$t_s = 1.12 t_h \sqrt{1.1 - l / \sqrt{d t_h}} \quad (8)$$

(8) for a length of at least $2\sqrt{d t_s}$.

(3) When $C = 0.10$ is used, the taper shall be 1:4.

(b) In sketch (b-1), $C = 0.17$ for forged circular heads integral with or butt welded to the vessel, where the flange thickness is not less than two times the shell thickness, the corner radius on the inside is not less than three times the flange thickness, and the welding meets all the requirements of NC-4000.

(c) In sketch (b-2), $C = 0.33m$ but not less than 0.2 for forged circular heads integral with or butt welded to the vessel, where the flange thickness is not less than the shell thickness and the corner radius on the inside is not less than 1.5 times the flange thickness. See Fig. NC-4243.1-1 sketches (a) and (b) for the special cases where $t_f = t_s$.

(d) In sketch (c), $C = 0.13$ for integral flat circular heads when the dimension d does not exceed 24 in. (610 mm), the ratio of thickness of the head to the dimension d is not less than 0.05 nor greater than 0.25, the head thickness t_h is not

less than the shell thickness t_s , the inside corner radius is not less than $0.25t$, and the construction is obtained by special techniques of upsetting and spinning the end of the shell, such as employed in closing header ends.

(e) In sketches (d) and (e), $C = 0.2$ for circular heads and covers bolted to the vessel as indicated in the figures. Note that Eq. (6) shall be used because of the extra moment applied to the cover by the bolting. When the cover plate is grooved for a peripheral gasket as shown in sketch (e), the net cover plate thickness under the groove or between the groove and the outer edge of the cover plate shall be not less than $d\sqrt{1.27Wh_C/Sd^3}$ for circular heads and covers.

(f) In sketches (f), (g), and (h), $C = 0.2$ for a circular plate inserted into the end of a vessel and held in place by a positive mechanical locking arrangement, and when all possible means of failure (by shear, tension, compression, or radial deformation, including flaring) resulting from pressure and differential thermal expansion are resisted using stresses consistent with this Article. Seal welding may be used, if desired.

(g) In sketch (i), $C = 0.17$ for circular covers, bolted with a full-face gasket, to shells, flanges, or side plates.

(h) In Fig. NC-4243-1 sketches (b), (c), (e), and (f), $C = 0.33m$ but not less than 0.3 when the dimensional requirements of NC-3358.3 are met.

(i) In Fig. NC-4243.1-1, $C = 0.33m$ but not less than 0.3 when the dimensional requirements of NC-3358.4 are met.

(j) In Fig. NC-4243-2 sketches (a) and (b), $C = 0.33m$ but not less than 0.2 when the dimensional requirements of NC-3358.3 are met.

NC-3326 Spherically Dished Covers With Bolting Flanges

NC-3326.1 Nomenclature.

The symbols used are defined as follows:

t	= minimum required thickness of head plate after forming, in.
L	= inside spherical or crown radius, in.
r	= inside knuckle radius, in.
P	= Design Pressure, psi
S	= maximum allowable stress value, psi
T	= flange thickness, in.

Page 111

M_o	= the total moment, in. lb, determined as in XI-3230 for heads concave to pressure, and XI-3260 for heads convex to pressure; except that for heads of the type shown in Fig. NC-3326.1-1 sketch (b), H_D and h_D shall be as defined below, and an additional moment, $H_r h_r^{14}$ shall be included:
H_r	= radial component of the membrane load in the spherical segment = $H_D \cot \beta_1$, lb, acting at the intersection of the inside of the flange ring with the center line of the dished cover thickness
h_r	= lever arm of H_r about centroid of flange ring, in.
H_D	= axial component of the membrane load in the spherical segment, lb, acting at the inside of the flange ring = $0.785 B^2 P$
h_D	= radial distance from the bolt circle to the inside of the flange

ring, in.

**FIG. NC-3326.1-1 SPHERICALLY DISHED
COVERS WITH BOLTING FLANGES**

FIG. NC-3326.1-1 SPHERICALLY DISHED COVERS WITH BOLTING FLANGES

14 Since Hh in some cases will subtract from the total moment, the moment in the flange ring when the internal pressure is zero may be the determining loading for the flange design.

β_1

= angle formed by the tangent to the center line of the dished cover thickness at its point of intersection with the flange ring, and a line perpendicular to the axis of the dished cover, where

$$\beta_1 = \arcsin \left(\frac{B}{2L + t} \right)$$

A

= outside diameter of flange, in.

B

= inside diameter of flange, in.

C

= bolt circle diameter, in.

NC-3326.2 Spherically Dished Heads With Bolting Flanges.

Circular spherically dished heads with bolting flanges, both concave and convex to the pressure, and conforming to the several types illustrated in Fig. NC-3326.1-1, shall be designed in accordance with the requirements of (a) and (b) below. For heads convex to pressure, the spherical segments shall be thickened, if necessary, to meet the requirements of NC-3133. The actual value of the total moment M_o may calculate to be either plus or minus for both the heads concave to pressure and the heads convex to pressure. However, for use in all of the formulas which follow, the absolute values for both P and M_o shall be used.

(a) Heads of the type shown in Fig. NC-3326.1-1 sketch (a):

(1) head thickness:

$$(9) t = 5PL/6S$$

(2) flange thickness, T :

for ring gasket:

$$T = Q + \sqrt{\frac{1.875M_o(C + B)}{SB(7C - 5B)}} \quad (10)$$

(10)

for full face gasket:

$$T = Q + \sqrt{Q^2 + \frac{3BQ(C - B)}{L}} \quad (11)$$

(11)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{7C - 5B} \right) \quad (12)$$

(12)

for heads with round bolting holes or where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{3C - B} \right) \quad (13)$$

(13)

for heads with bolting holes slotted through edge of head;

Page 112

(3) the larger of the values of t given by (1) and (2) above shall be used.

(b) Heads of the type shown in Fig. NC-3326.1-1 sketch (b):

(1) head thickness:

$$(14) t = 5PL/6S$$

(2) flange thickness for ring gaskets shall be calculated as follows:

(a) for heads with round bolting holes:

$$T = Q + \sqrt{\frac{1.875M_o(C + B)}{SB(7C - 5B)}} \quad (15)$$

(15)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{7C - 5B} \right) \quad (16)$$

(16)

(b) for heads with bolting holes slotted through the edge of the head:

$$T = Q + \sqrt{\frac{1.875M_o(C + B)}{SB(3C - B)}} \quad (17)$$

(17)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{3C - B} \right) \quad (18)$$

(18)

(3) flange thickness for full face gaskets shall be calculated by the following equation:

$$T = Q + \sqrt{Q^2 + \frac{3BQ(C - B)}{L}} \quad (19)$$

(19)

The value of Q in Eq. (19) is calculated by Eq. (16) for round bolting holes or by Eq. (18) for bolting holes slotted through the edge of the head [see (2) above].

(4) the required flange thickness shall be T as calculated in (2) or (3) above, but in no case less than the value of t calculated in (1).

NOTE: These equations are approximate in that they do not take into account continuity between the flange ring and the dished head. A more exact method of analysis which takes this into account may be used. Such a method may parallel the method of analysis and allowable stresses for flange design in Appendix XI. The dished portion of a cover designed under this rule may, if welded, require evaluation of any welded joint.

NC-3327 Quick Actuating Closures

Closures other than the multibolted type designed to provide access to the contents space of a component shall have the locking mechanism or locking device so designed that failure of any one locking element or component in the locking mechanism cannot result in the failure of all other locking elements and the release of the closure. Quick actuating closures shall be so designed and installed that it may be determined by visual external observation that the holding elements are in good condition and that their locking elements, when the closure is in the closed position, are in full engagement.

NC-3327.1 Positive Locking Devices.

Quick actuating closures that are held in position by positive locking devices and that are fully released by partial rotation or limited movement of the closure itself or the locking mechanism and any closure that is other than manually operated shall be so designed that when the vessel is installed the conditions of (a) through (c) below are met.

(a) The closure and its holding elements are fully engaged in their intended operating position before pressure can be built up in the vessel.

(b) Pressure tending to force the closure clear of the vessel will be released before the closure can be fully opened for access.

(c) In the event that compliance with (a) and (b) is not inherent in the design of the closure and its holding elements, provision shall be made so that devices to accomplish this can be added when the vessel is installed.

NC-3327.2 Manual Operation.

Quick actuating closures that are held in position by a locking device or mechanism that requires manual operation and are so designed that there will be leakage of the contents of the vessel prior to disengagement of the locking elements and release of closure need not satisfy NC-3327.1, but such closures shall be equipped with an audible or visible warning device that will serve to warn the operator if pressure is applied to the vessel before the closure and its holding elements are fully engaged in their intended position and further will serve to warn the operator if an attempt is made to operate the locking mechanism or device before the pressure within the vessel is released.

NC-3327.3 Pressure Indicating Device.

When installed, all vessels having quick actuating closures shall be provided with a pressure indicating device visible from the operating area.

Page 113

**FIG. NC-3329(b)-1 EXAMPLE OF
TUBE SPACING WITH PITCH OF HOLES
EQUAL IN EVERY ROW**

FIG. NC-3329(b)-1 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES EQUAL IN EVERY ROW

**FIG. NC-3329(b)-2 EXAMPLE OF
TUBE SPACING WITH PITCH OF HOLES
UNEQUAL IN EVERY SECOND ROW**

FIG. NC-3329(b)-2 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES UNEQUAL IN EVERY SECOND ROW

NC-3329 Ligaments

(a) The symbols used are defined as follows:

p	= longitudinal pitch of tube holes, in.
p_1	= unit length of ligament, in.
p'	= diagonal pitch of tube holes, in.
d	= diameter of tube holes, in.
n	= number of tube holes in length p_1

(b) When a cylindrical shell is drilled for tubes in a line parallel to the axis of the shell for substantially the full length of the shell as shown in Figs. NC-3329(b)-1 through NC-3329(b)-3, the efficiency of the ligaments between the tube holes shall be determined by (1) or (2) below:

(1) when the pitch of the tube holes on every row is equal [Fig. NC-3329(b)-1], the equation is:

$$\frac{p - d}{p} = \text{efficiency of ligament}$$

(2) when the pitch of tube holes on any one row is unequal [Figs. NC-3329(b)-2 and NC-3329(b)-3], the formula is:

$$\frac{p_1 - nd}{p_1} = \text{efficiency of ligament}$$

(c) The strength of ligaments between tube holes measured circumferentially shall be at least 50% of the strength of ligaments of similar dimensions taken in a line parallel to the axis of the cylindrical shell.

(d) When a cylindrical shell is drilled for tube holes so as to form diagonal ligaments, as shown in Fig. NC-3329(d)-1, the efficiency of these ligaments shall be that given by the diagram in Fig. NC-3329(d)-2. The pitch of tube holes shall be measured either on the flat plate before rolling or on the middle line of the plate after rolling. To use the diagram in Fig. NC-3329(d)-2, compute the value of p'/p_1 and also the efficiency of the longitudinal ligament. Next, find in the diagram the vertical line corresponding to the longitudinal efficiency of the ligament and follow this line vertically to the point where it intersects the diagonal line representing the ratio of p'/p_1 . Then project this point horizontally to the left and read the diagonal efficiency of the ligament on the scale at the edge of the diagram. The shell thickness and the maximum allowable pressure shall be based on the ligament that has the lower efficiency.

(e) When tube holes in a cylindrical shell are arranged in symmetrical groups which extend a distance greater than the inside diameter of the shell along lines parallel to the axis and the same spacing is used for each group, the efficiency for one of the groups shall be not less than the efficiency on which the maximum allowable pressure is based.

(f) The average ligament efficiency in a cylindrical shell, in which the tube holes are arranged along lines parallel to the axis with either uniform or nonuniform spacing, shall be computed by the following rules and shall satisfy the requirements of both (1) and (2) below.¹⁵

(1) For a length equal to the inside diameter of the shell for the position which gives the minimum efficiency, the efficiency shall not be less than that on which the maximum allowable pressure is based. When the diameter of the shell exceeds 60 in. (1520 mm), the length shall be taken as 60 in. (1520 mm) in applying this rule.

¹⁵ The rules in this paragraph apply to ligaments between tube holes and not to single openings. They may give lower efficiencies in some cases than those for symmetrical groups which extend a distance greater than the inside diameter of the shell as covered in (c). When this occurs, the efficiencies computed by the rules under (b) shall govern.

(2) For a length equal to the inside radius of the shell for the position which gives the minimum efficiency,

the efficiency shall be not less than 80% of that on which the maximum allowable pressure is based. When the radius of the shell exceeds 30 in. (762 mm), the length shall be taken as 30 in. (762 mm) in applying this rule.

FIG. NC-3329(b)-3 EXAMPLE OF TUBE SPACING WITH PITCH HOLES VARYING IN EVERY SECOND AND THIRD ROW

**FIG. NC-3329(d)-1 EXAMPLE OF
TUBE SPACING WITH TUBE HOLES
ON DIAGONAL LINES**

FIG. NC-3329(d)-1 EXAMPLE OF TUBE SPACING WITH TUBE HOLES ON DIAGONAL LINES

(g) For holes which are not in line, placed longitudinally along a cylindrical shell, the rules in (f) above for calculating efficiency shall hold, except that the equivalent longitudinal width of a diagonal ligament shall be used. To obtain the equivalent width, the longitudinal pitch of the two holes having a diagonal ligament shall be multiplied by the efficiency of the diagonal ligament. The efficiency to be used for the diagonal ligaments is given in Fig. NC-3329(g)-1.

NC-3330 OPENINGS AND REINFORCEMENT

NC-3331 General Requirements for Openings

(a) Openings in cylindrical or conical portions of vessels or in formed heads shall preferably be circular, elliptical, or obround. When the long dimension of an elliptical, or obround, opening exceeds twice the short dimensions, the reinforcement across the short dimensions shall be increased as necessary to provide against excessive distortion due to twisting moment.

(b) Openings may be of other shapes than those given in (a) and all corners shall be provided with a suitable radius.

(c)(1) The rules for reinforcement of openings given in NC-3330 are intended to apply to openings not exceeding the following:

(a) for vessels 60 in. (1520 mm) diameter and less, one half the vessel diameter but not to exceed 20 in. (508 mm);

(b) for vessels over 60 in. (1520 mm) diameter, one-third the vessel diameter but not to exceed 40 in. (1000 mm).

(2) Larger openings shall be given special attention. Two-thirds of the required reinforcement shall be within $\frac{1}{2}r$ parallel to the vessel surface and measured from the edge of the opening, where r is the radius of the finished opening. The limit normal to the vessel wall is the smaller of the limits specified in NC-3334.2. Special consideration shall be given to the fabrication details used and examination employed. Reinforcement often may be advantageously obtained by use of heavier shell plate for a vessel course or inserted locally around the opening. Welds may be ground to concave contour and the inside corners of the opening rounded to a generous radius to reduce stress concentrations.

(d)

allowance.

(e) Any type of opening may be located in a welded joint.

NC-3332 Reinforcement Requirements for Openings in Shells and Formed Heads

NC-3332.1 Openings Not Requiring Reinforcement.

Reinforcement shall be provided in amount and distribution such that the requirements for area of reinforcement are satisfied for all planes through the center of the opening and normal to the surface of the vessel, except that single circular openings need not be provided with reinforcement if the openings have diameters equal to or less than 2 in. nominal pipe size (DN 50).

NC-3332.2 Required Area of Reinforcement.

The total cross-sectional area of reinforcement A required in any given plane for a vessel under internal pressure shall not be less than

$$A = dt_r F$$

where

d

= finished diameter of a circular opening or finished dimension (chord length) of an opening on the plane being considered for elliptical and obround openings in corroded condition, in.

F

= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of a vessel. A value of 1.00 shall be used for all configurations except that Fig. NC-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.

t_r

= the required thickness of a shell or head computed by the rules of this Article for the Design Pressure, in., except that:

(a) when the opening and its reinforcement are entirely within the spherical portion of a torispherical head, t_r is the thickness required by NC-3324.8(b) using $M = 1$;

(b) when the opening is in a cone, t_r is the thickness required for a seamless cone of diameter D measured where the nozzle axis pierces the inside wall of the cone;

(c) when the opening and its reinforcement are in an ellipsoidal head and are located entirely within a circle, the center of which coincides with the center of the head and the diameter of which is equal to 80% of the shell diameter, t_r is the thickness required for a seamless sphere of radius $K_1 D$, where D is the shell diameter and K_1 is given by Table NC-3332.2-1.

FIG. NC-3332.2-1 CHART FOR DETERMINING
THE VALUE OF F

FIG. NC-3332.2-1 CHART FOR DETERMINING THE VALUE OF F

At least one-half of the required reinforcing shall be on each side of the center line of the opening.

NC-3332.3 Reinforcement for External Pressure.

The reinforcement required for openings in vessels designed for external pressure need only be 50% of that required in the formula for area in NC-3332.2, except that t_r is the wall thickness required by the rules for vessels under external pressure.

NC-3332.4 Reinforcement for Both Internal and External Pressure.

Reinforcement of vessels subject to both internal and external pressures shall meet the

Page 118

requirements of NC-3332.2 for internal pressure and of NC-3332.3 for external pressure.

TABLE NC-3332.2-1
VALUES OF SPHERICAL RADIUS FACTOR K_1
Equivalent Spherical Radius = $K_1 D$; $D/2h$ = Axis Ratio;
Interpolation Permitted for Intermediate Values

$D/2h$	...	3.0	2.8	2.6	2.4	2.2
K_1	...	1.36	1.27	1.18	1.08	0.99
$K/2h$	2.0	1.8	1.6	1.4	1.2	1.0
K_1	0.90	0.81	0.73	0.65	0.57	0.50

TABLE NC-3332.2-1 VALUES OF SPHERICAL RADIUS FACTOR K_1

NC-3333 Reinforcement Required for Openings in Flat Heads

(a) Flat heads that have an opening with a diameter that does not exceed one-half of the head diameter shall have a total cross-sectional area of reinforcement not less than that given by the equation

$$A = 0.5dt_r$$

where d is defined in NC-3332.2 and t_r is the thickness in inches which meets the requirements of NC-3325 in the absence of the opening.

(b) As an alternative to (a) above, the thickness of flat heads may be increased to provide the necessary opening reinforcement as follows:

(1) in Eq. (5) of NC-3325.2 by using $2C$ or 0.75 in place of C , whichever is less;

(2) in Eq. (6) of NC-3325.2, by doubling the quantity under the square root sign.

(c) Flat heads that have an opening with a diameter that exceeds one-half of the head diameter or shortest span, as defined in NC-3325.1, shall be designed as follows.

(1) When the opening is a single, circular, centrally located opening and when the shell-head juncture is integrally formed or integrally attached by a full penetration weld similar to those shown in Fig. NC-3325-1 sketch (a), (b-1), (b-2), or (c), the head shall be designed according to Appendix XIX and related parts of Appendix XI. The required head thickness does not have to be calculated according to NC-3325, since the head thickness which satisfies all the requirements of Appendix XIX also satisfies the intent of NC-3325. The opening in the head may have a nozzle which is integrally formed or integrally attached by a full penetration weld, or it may be an opening without an attached nozzle or hub.

(2) When the opening is of any other type than that described in (1) above, no specific rules are given. Consequently, the requirements of NC-1100(c) shall be met.

NC-3334 Limits of Reinforcement

The boundaries of the cross-sectional area in any plane normal to the vessel wall and passing through the center of the opening and within which metal shall be located in order to have value as reinforcement are designated as the limits of reinforcement for that plane and are given in the following subparagraphs.

NC-3334.1 Limits of Reinforcement Along the Vessel Wall.

The limits of reinforcement, measured along the midsurface of the nominal wall thickness, shall meet the following:

(a) 100% of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) the diameter of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus the sum of the thicknesses of the vessel wall and the nozzle wall;

(b) two-thirds of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) $r + 0.5\sqrt{Rt}$, where R is the mean radius of shell or head, t is the nominal vessel wall thickness, r is the radius of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus two-thirds the sum of the thicknesses of the vessel wall and the nozzle wall.

NC-3334.2 Limits of Reinforcement Normal to the Vessel Wall.

The limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to the lesser of (a) or (b) below:

(a) $2\frac{1}{2}$ times the nominal shell thickness less corrosion allowance;

(b) $2\frac{1}{2}$ times the nozzle wall thickness less corrosion allowance, plus the thickness of any added reinforcement exclusive of weld metal on the side of the shell under consideration.

NC-3335 Metal Available for Reinforcement

NC-3335.1 Openings.

Metal within the limits of reinforcement that may be considered to have reinforcing value shall be that given in (a) through (d) below:

(a) metal in the vessel wall over and above the thickness required to resist pressure and the thickness specified as

corrosion allowance. The area in the vessel wall available as reinforcement is the larger of the values of A_1 given by:

$$A_1 = (t - Ft_r)d$$

or

$$A_1 = 2(t - Ft_r)(t + t_n)$$

(b) metal over and above the thickness required to resist pressure and the thickness specified as corrosion allowance in that part of a nozzle wall extending outside the vessel wall. The maximum area in the nozzle wall available as reinforcement is the lesser of the values of A_2 given by:

$$A_2 = (t_n - t_{rn})5t$$

or

$$A_2 = (t_n - t_{rn})(5t_n + 2t_e)$$

(c) all metal in the nozzle wall extending inside the vessel wall may be included after proper deduction for corrosion allowance on all the exposed surface is made. No allowance shall be taken for the fact that a differential pressure on an inwardly extending nozzle may cause opposing stress to that of the stress in the shell around the opening where

A_1	= area in excess thickness in the vessel wall available for reinforcement, sq in. (NC-3334)
A_2	= area in excess thickness in the nozzle wall available for reinforcement, sq in. (NC-3334)
F	= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of a vessel. A value of 1.00 shall be used for all configurations, except that Fig. NC-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.
t_e	= thickness of attached reinforcing pad or height of the largest 60 deg. right triangle supported by the vessel and nozzle outside diameter projected surfaces and lying completely within the area of integral reinforcement, in. [Fig. NC-3335(b)-1]
t	= nominal thickness of the vessel wall, less corrosion allowance, in.
t_r	= required thickness of a seamless shell or head as defined in NC-3332.2, in.
t_n	= nominal thickness of nozzle wall, less corrosion allowance, in.
t_{rn}	= required thickness of a seamless nozzle wall, in.
d	= diameter in the plane under consideration of the finished opening in its corroded condition, in. (NC-3332.2)

(d) metal added as reinforcement and metal in attachment welds.

NC-3335.2 Reinforcement of Multiple Openings

(a) When any two openings in a group of two or more openings are spaced at less than two times their average diameter so that their limits of reinforcement overlap, the two openings shall be reinforced in the plane connecting the centers (Fig. NC-3335.2-1) in accordance with NC-3330 through NC-3336, with a combined reinforcement that has an area equal to the combined area of the reinforcement required for separate openings. No portion of the cross section is to be considered as applying to more than one opening, or to be evaluated more than once in a combined area. The

following additional requirements shall also apply.

(1) When the distance between the centers of the openings is greater than $1\frac{1}{3}$ times their average diameter, the area of reinforcement between them shall not be less than 50% of the total required for these openings.

(2) When the distance between the centers of the openings is less than $1\frac{1}{3}$ times their average diameter, no credit for reinforcement shall be taken for any of the material between these openings, and the openings shall be reinforced as described in (b) below.

(b) Any number of adjacent openings, in any arrangement, may be reinforced for an assumed opening of a diameter enclosing all such openings. The diameter of the assumed opening shall not exceed the following:

(1) for vessels 60 in. in diameter and less, one-half the vessel diameter, but not to exceed 20 in. (508 mm);

(2) for vessels over 60 in. in diameter, one-third the vessel diameter, but not to exceed 40 in.

(c) When a group of openings is reinforced by a thicker section butt welded into the shell or head, the edges of the inserted section shall be tapered as prescribed in NC-3361.

(d) When a series of two or more openings in a pressure vessel is arranged in a regular pattern,

Page 120

reinforcement of the openings may be provided in accordance with the requirements of NC-3329.

FIG. NC-3335(b)-1 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT DIMENSION

FIG. NC-3335(b)-1 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT DIMENSION

GENERAL NOTES:

- (1) Hatched area represents overlapping of the reinforcement limits.
- (2) Each cross section indicated by a straight line a-a must be investigated for adequacy of reinforcement.
- (3) Heavy circles represent openings, and light circles represent limits of reinforcement.

FIG. NC-3335.2-1 ARRANGEMENT OF MULTIPLE OPENINGS

FIG. NC-3335.2-1 ARRANGEMENT OF MULTIPLE OPENINGS

NC-3335.3 Flued Openings in Formed Heads

(a) Flued openings in formed heads made by inward or outward forming of the head plate shall meet the requirements for reinforcement in NC-3332.

(b) The minimum depth of flange of a flued opening exceeding 6 in. in any inside dimension, when not stayed by an attached pipe or flue, shall equal $3t_r$ or $(t_r + 3)$ in., whichever is less, where t_r is the required head thickness. The depth of flange shall be determined by placing a straight edge across the side opposite the flued opening along the major axis and measuring from the straight edge to the edge of the flanged opening [Fig. NC-3335.3(b)-1].

(c) The minimum width of bearing surface for a gasket on a self-sealing flued opening shall be in accordance with NC-3363.7.

NC-3336 Strength of Reinforcing Material

Material used for reinforcement shall preferably be the same as that of the vessel wall. If the material of the nozzle wall or reinforcement has a lower design stress value S than that for the vessel material, the

Page 122

amount of area provided by the nozzle wall or reinforcement in satisfying the requirements of NC-3332 shall be taken as the actual area provided multiplied by the ratio of the nozzle or reinforcement material design stress value to the vessel material design stress value. No reduction in the reinforcing required shall be taken for the increased strength of

reinforcing material and weld metal having higher design stress values than that of the material of the vessel wall. Deposited weld metal outside of either the vessel wall or any reinforcing pad used as reinforcement shall be credited with an allowable stress value equivalent to the weaker of the materials connected by the weld. Vessel-to-nozzle or pad-to-nozzle attachment weld metal within the vessel wall or within the pad may be credited with a stress value equal to that of the vessel wall or pad, respectively.

Maximum depth of flange:

the smaller of $3t_r$ or $t_r + 3$ in.
when d exceeds 6 in.

**FIG. NC-3335.3(b)-1 MINIMUM DEPTH FOR
FLANGE OF FLUED OPENINGS**

FIG. NC-3335.3(b)-1 MINIMUM DEPTH FOR FLANGE OF FLUED OPENINGS

NC-3336.1 Strength of Weld.

On each side of the plane defined in NC-3334, the strength of the attachment joining the vessel wall and reinforcement or any two parts of the attached reinforcement shall be at least equal to the lesser of (a) or (b) below:

(a) the strength in tension of the cross section of the element of reinforcement being considered;

(b) the strength in tension of the area defined in NC-3332 less the strength in tension of the reinforcing area which is integral in the vessel wall.

NC-3336.2 Strength of Attachment.

The strength of the attachment joint shall be considered for its entire length on each side of the plane of the area of reinforcement defined in NC-3334. For obround openings, consideration shall also be given to the strength of the attachment joint on one side of the plane transverse to the parallel sides of the opening which passes through the center of the semicircular end of the opening.

NC-3350 DESIGN OF WELDED CONSTRUCTION

NC-3351 Welded Joint Categories

The term *category* defines the location of a joint in a vessel but not the type of joint. The categories are for use in specifying special requirements regarding joint type and method of examination for certain welded joints. Since these special requirements, which are based on service, material, and thickness, do not apply to every welded joint, only those joints to which special requirements apply are included in the categories. The special requirements apply to joints of a given category only when specifically stated. The joints included in each category are designated as joints of Categories A, B, C, and D. Figure NC-3351-1 illustrates typical joint locations included in each category.

NC-3351.1 Category A.

Category A comprises longitudinal welded joints within the main shell, communicating chambers,¹⁶ transitions in diameter, or nozzles; any welded joint within a sphere, within a formed or flat head, or within the side plates¹⁷ of a flat-sided vessel; circumferential welded joints connecting hemispherical heads to main shells, to transitions in diameters, to nozzles, or to communicating chambers.

NC-3351.2 Category B.

Category B comprises circumferential welded joints within the main shell, communicating chambers,¹⁴ nozzles, or transitions in diameter including joints between the transition and a cylinder at either the large or small end; circumferential welded joints connecting formed heads other than hemispherical to main shells, to transitions in diameter, to nozzles, or to communicating chambers.

NC-3351.3 Category C.

Category C comprises welded joints connecting flanges, Van Stone laps, tubesheets, or flat heads to main shell, to formed heads, to transitions in diameter, to nozzles, or to communicating chambers¹⁴ and any welded joint connecting one side plate¹⁵ to another side plate of a flat-sided vessel.

NC-3351.4 Category D.

Category D comprises welded joints connecting communicating chambers¹⁴ or nozzles to main shells, to spheres, to transitions in diameter, to heads, or to flat-sided vessels and those joints connecting nozzles to communicating chambers. For nozzles at the small end of a transition in diameter, see Category B.

NC-3352 Permissible Types of Welded Joints

The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints

between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle α not exceeding 30 deg. are considered as meeting the requirements for butt joints. Figure NC-3352-1 shows typical butt welds for each category joint.

16 Communicating chambers are defined as appurtenances to the vessel which intersect the shell or heads of a vessel and form an integral part of the pressure retaining enclosure, such as sumps.

17 Side plates of a flat-sided vessel are defined as any of the flat plates forming an integral part of the pressure retaining enclosure.

NC-3352.1 Joints of Category A.

All welded joints of Category A shall meet the fabrication requirements

Page 123

of NC-4241 and shall be capable of being examined in accordance with NC-5210.

FIG. NC-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

FIG. NC-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

NC-3352.2 Joints of Category B.

All welded joints of Category B shall meet the fabrication requirements of NC-4242 and shall be capable of being examined in accordance with NC-5220.

NC-3352.3 Joints of Category C.

All welded joints of Category C shall meet the fabrication requirements of NC-4243 and shall be capable of being examined in accordance with NC-5230.

NC-3352.4 Joints of Category D.

All welded joints of Category D shall be in accordance with the requirements of NC-3359 and one of (a) through (e) below.

(a) *Butt Welded Nozzles.* Nozzles shall meet the fabrication requirements of NC-4244(a) and shall be capable of being examined in accordance with NC-5241. The minimum dimensions and geometrical requirements of Fig. NC-4244(a)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm), minimum

(b) *Full Penetration Corner Welded Nozzles.* Nozzles shall meet the fabrication requirements of NC-4244(b) and shall be capable of being examined as required in NC-5241. Inserted type necks having added reinforcement in the form of a separate reinforcing plate shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of $\frac{1}{2}t_{\min}$. The minimum dimensions of Fig. NC-4244(b)-1 shall be met where:

$t_{\min}$	= the lesser of $\frac{3}{4}$ in. or the thickness of the thinner of the parts joined
t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm), minimum
t_e	= thickness of reinforcing element, in.

(c) *Use of Deposited Weld Metal for Openings and Nozzles*

(1) Nozzles shall meet the requirements of NC-4244(c) and shall be capable of being examined in accordance with NC-5241.

(2) When the deposited weld metal is used as reinforcement, the coefficients of thermal expansion of the base metal, the weld metal, and the nozzle shall not differ by more than 15% of the lowest coefficient involved.

(3) The minimum dimensions of Fig. NC-4244(c)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less

(4) The corners of the end of each nozzle, extending less than $\sqrt{d}t_n$ beyond the inner surface of the part penetrated, shall be rounded to a radius of one-half the thickness t_n of the nozzle or $\frac{3}{4}$ in., whichever is less.

FIG. NC-3352-1 TYPICAL BUTT JOINTS

FIG. NC-3352-1 TYPICAL BUTT JOINTS

(d) Attachment of Nozzles Using Partial Penetration Welds

(1) Partial penetration welds shall meet the requirements of NC-4244(d) and are limited to those used to connect nozzles 2 in. nominal pipe size or less, as shown in Fig. NC-4244(d)-1. For inserted nozzles without reinforcing elements, two partial penetration welds may be used of any desired combination of fillet, single bevel, and single J-welds. Inserted-type nozzles having added reinforcement in the form of a separate reinforcing plate shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of $\frac{1}{2}t_{\min}$. The welds attaching the nozzle to the vessel wall and to the reinforcement shall consist of one of the combinations given in (a) through (c) below:

(a) a single bevel or single J-weld in the shell plate and a single bevel and single J-weld in each reinforcement plate. The dimension t_w of each weld shall be not less than $0.7t_{\min}$ [Fig. NC-4244(d)-1 sketch (g)].

(b) a full penetration groove weld in the shell plate and a fillet, single bevel, or single J-weld with a weld dimension t_w not less than $0.7t_{\min}$ in each reinforcement plate [Fig. NC-4244(d)-1 sketch (f)];

(c) a full penetration groove weld in each reinforcement plate and a fillet, single bevel, or single J-weld with a weld dimension t_w not less than $0.7t_{\min}$ in the shell plate [Fig. NC-4244(d)-1 sketch (e)]. These welds shall be capable of being examined in accordance with the requirements of NC-5241.

(2) The minimum dimensions of Fig. NC-4244(d)-1 shall be met where:

$t_1 + t_2$	$= 1/4 t_{\min}; t_1 \text{ or } t_2 \text{ not less than the lesser of } 1/4 \text{ in. or } 0.7t_{\min}$
$t_{\min}$	$= \text{the lesser of } 3/4 \text{ in. or the thickness of the thinner of the parts joined}$
t_e	$= \text{thickness of reinforcement element, in.}$

Page 125

t	$= \text{nominal thickness of part penetrated, in.}$
t_n	$= \text{nominal thickness of penetrating part, in.}$
t_c	$= 0.7t_n \text{ or } 1/4 \text{ in., whichever is less}$
c	$= 1/2 t_{\min}$
t_w	$= 0.7t_n \text{ except } t_w = 0.7t_{\min} \text{ for sketch (e)}$

(e) *Attachment of Fittings With Internal Threads.*¹⁸ The attachment of internally threaded fittings shall meet the requirements of (1) through (3) below:

(1) except as provided for in (2) and (3), the provisions of NC-4244(e) shall be met. The minimum weld dimensions shall be as shown in Fig. NC-4244(d)-1 where:

$t_{\min}$	$= \text{lesser of } 3/4 \text{ in. or the thickness of the parts joined}$
t_c	$= 1/4 \text{ in., minimum}$

sketches (a) and (b)

$$t_1 + t_2 = 1/4 t_{\min}$$

sketch (c)

$$t_w = \text{thickness of Sch. 160 pipe (ANSI B36.10)} \quad t_1 + t_2 \text{ not less than the lesser of } 1/4 \text{ in. or } 0.7t_{\min}$$

sketch (d)

$$t_w = 0.7t_{\min}$$

(2) fittings shown in Fig. NC-4244(d)-1 sketches (a-2), (b-2), (c-2), and (d) not exceeding 2 in. nominal pipe size may be attached by welds that are exempt from size requirements other than those specified in NC-3359;

(3)(a) when internally threaded fittings and bolting pads not exceeding 3 in. nominal pipe size (DN 80) are attached to vessels having a wall thickness not greater than $3/8$ in. (76 mm) by a fillet weld deposited from the outside only, the welds shall comply with the dimensions shown in Fig. NC-4244(e)-2. These openings do not require reinforcement other than that inherent in the construction as permitted in NC-3332.1.

(b) if the opening exceeds $5/8$ in. (136 mm) in any direction or is greater than one-half the vessel diameter, the opening shall be reinforced in accordance with NC-3332 with the nozzle or other connections attached, using a suitable detail in Fig. NC-4244(e)-1.

NC-3354 Structural Attachment Welds

Welds for structural attachments shall meet the requirements of NC-4430.

¹⁸ Written for fittings with internal threads but also applicable to externally threaded and socket or butt welded fittings.

NC-3355 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and complete joint penetration, except as otherwise permitted in NC-3352.4.

NC-3356 Fillet Welds

(a) Fillet welds may be used as strength welds within the limitations given in NC-3352 and Fig. NC-4427-1. Particular care shall be taken in the layout of joints in which fillet welds are to be used in order to assure complete fusion at the root of the fillet.

(b) Corner or tee joints may be made with fillet welds, provided the plates are properly supported independently of such welds, except that independent supports are not required for joints used for lugs or clips.

(c) The allowable load on fillet welds shall equal the product of the weld area based on minimum leg dimensions, the allowable stress value in tension of the material being welded, and a joint efficiency of 0.55.

NC-3357 Welded Joints Subject to Bending Stresses

Except where specific details are permitted in other paragraphs, fillet welds shall be added where necessary to reduce stress concentration. The requirements of NC-3356(b) apply.

NC-3358 Design Requirements for Head Attachments

NC-3358.1 Skirt Length of Formed Heads

(a) Ellipsoidal and other types of formed heads, concave or convex to the pressure, shall have a skirt length not less than that shown in Fig. NC-3358.1(a)-1.

(b) A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections, as shown in Fig. NC-3358.1(a)-1, shall be provided at joints between formed heads and shells that differ in thickness by more than one-fourth the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. When a taper is required on any formed head thicker than the shell and intended for butt welded attachment [Fig. NC-3358.1(a)-1], the skirt shall be long enough so that the required length of taper does not extend beyond the tangent line.

NC-3358.2 Unstayed Flat Heads Welded to Shells.

The requirements for the attachment of unstayed flat heads welded to shells are given in NC-3325, NC-3358.3, and NC-3358.4.

Page 126

Page 127

GENERAL NOTES [sketches (a) and (b)] :

- (a) Length of required taper ℓ may include the width of the weld.
- (b) In all cases, the projected length of taper ℓ shall be not less than $3y$.
- (c) The shell plate center line may be on either side of the head plate center line.

GENERAL NOTES (sketches (c) and (d)):

- (a) In all cases ℓ shall be not less than 3 times y when t_h exceeds $1.25t_s$; minimum length of skirt is $3t_h$, but need not exceed 1-1/2 in. except when necessary to provide required length of taper.
- (b) When t_h is equal to or less than $1.25t_s$, length of skirt shall be sufficient for any required taper.
- (c) Length of required taper ℓ may include the width of the weld.
- (d) The shell plate center line may be on either side of the head plate center line.

FIG. NC-3358.1(a)-1 HEADS ATTACHED TO SHELLS

FIG. NC-3358.1(a)-1 HEADS ATTACHED TO SHELLS

NC-3358.3 Head Attachments Using Corner Joints.

When shells, heads, or other pressure parts are welded to a forged or rolled plate to form a corner joint, as in Figs. NC-4243-1 and NC-4243-2, the joint shall meet the applicable requirements of (a) through (f) below.

(a) On the cross section through the welded joint, the line of fusion between the weld metal and the forged or rolled plate being attached shall be projected on planes both parallel to and perpendicular to the surface of the plate being attached, in order to determine the dimensions a and b , respectively.

(b) For flange rings of bolted flanged connections and for flat heads and unsupported tubesheets with a projection having holes for a bolted connection, the sum of a and b shall be not less than three times the nominal thickness of the abutting pressure part.

(c) For supported tubesheets with a projection having holes for a bolted connection, the sum of a and b shall not be less than two times the nominal wall thickness of the abutting pressure part. A supported tubesheet is defined as one in which not less than 80% of the pressure load on the tubesheet is carried by tubes, stays, or braces.

(d) For other components, the sum of a and b shall be not less than two times the nominal wall thickness of the abutting pressure part. Examples of such components are flat heads and supported and unsupported tubesheets without a projection having holes for a bolted connection.

(e) Other dimensions of the joint shall be in accordance with details shown in Figs. NC-4243-1 and NC-4243-2 where:

(1) Fig. NC-4243-1

Sketches (a), (b), and (c)

(a) for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle not greater than 45 deg. measured from the face:

$$\begin{aligned} t_c &= 0.7 t_n \text{ or } \frac{1}{4} \text{ in., whichever is less} \\ t_w &= \text{the lesser of } t_n/2 \text{ or } t/4 \\ t, t_n &= \text{nominal thickness of welded parts, in.} \end{aligned}$$

(b) for all other material forms and for forged tubesheets, forged flat heads, and forged flanges with the weld preparation bevel angle greater than 45 deg. measured from the face:

$$\begin{aligned} t_c &= 0.7 t_n \text{ or } \frac{1}{4} \text{ in., whichever is less} \\ t_w &= \text{the lesser of } t_n \text{ or } t/2 \\ t, t_n &= \text{nominal thicknesses of welded parts, in.} \end{aligned}$$

Sketch (d)

$$t, t_n = \text{nominal thickness of welded parts, in., either leg of fillet weld} = 0.25 t_n \text{ but not less than } \frac{1}{4} \text{ in.}$$

Sketches (e) and (f)

$$\begin{aligned} t, t_n &= \text{nominal thickness of welded parts, in.} \\ t_c &= 0.7 t_n \text{ or } \frac{1}{4} \text{ in., whichever is less} \end{aligned}$$

 t_r =required thickness of shell, in.
 $a + b$ not less than $3t_s$
 c not less than t_s

(f) In Fig. NC-4243-1,

t_c	= $0.7 t_n$ or $\frac{1}{4}$ in., whichever is less
t_w	= the lesser of t_n or $t/2$
t_s, t_n	= nominal thicknesses, in.

(g) Joint details that have a dimension through the joint less than the thickness of the shell, head, or other pressure part, or that provide eccentric attachment are not permissible.

NC-3358.4 Flat Heads and Tubesheets With Hubs.

Hubs for butt welding to the adjacent shell, head, or other pressure part, as in Fig. NC-4243.1-1, shall not be machined from rolled plate. The component having the hub shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material, in a direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen (subsize if necessary) taken in this direction and as close to the hub as is practical. In Fig. NC-4243.1-1, the minimum dimensions are as follows:

Sketch (a)

r not less than $1.5t_s$

Sketch (b)

r not less than $1.5t_s$ and e not less than t_s

Sketch (c)

h not less than $1.5t_s$

Sketch (d)

r not less than $3t_f$

Sketch (e)

t_f not less than $2t_s$

r not less than $3t_f$

e not less than t_f

NC-3359 Design Requirements for Nozzle Attachment Welds

In addition to the requirements of NC-3352.4, the minimum design requirements for nozzle attachment welds are given in (a) and (b) below.

(a) *Required Weld Strength.* Sufficient welding shall be provided on either side of the line through the center of the opening parallel to the longitudinal axis of the shell to develop the strength of the reinforcing parts as required in NC-3336, through shear or tension in the weld, whichever is applicable. The strength of groove welds shall be based on the area subjected to shear or to tension. The strength of fillet welds shall be based on the area subjected to shear, computed on the minimum leg dimension. The inside diameter of a fillet weld shall be used in figuring its length. Calculations are not required when full penetration welds are used.

(b) *Allowable Stress Values for Welds.* The allowable stress values for groove and fillet welds and for shear in nozzles, in percentage of stress values for the vessel material, are as follows:

Nozzle wall shear	70%
Groove weld tension	74%
Groove weld shear	60%
Fillet weld shear	49%

NC-3360 SPECIAL VESSEL REQUIREMENTS

NC-3361 Tapered Transitions

A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections (Fig. NC-3361-1) shall be provided at joints between sections that differ in thickness by more than one-fourth of the thickness of the thinner section or by more than $\frac{1}{8}$ in., whichever is less. The transition may be formed by any process that will provide a uniform taper. The weld may be in the tapered section or adjacent to it. This also applies when there is a reduction in thickness within a spherical shell or cylindrical shell course and to a taper at a Category A joint within a formed head. Provisions for tapers at circumferential butt welded joints connecting formed heads to main shells are contained in NC-3358.1(b).

NC-3362 Bolted Flange and Studded Connections

(a) It is recommended that the dimensional requirements of bolted flange connections to external piping conform to ANSI Standard B16.5, Steel Pipe Flanges and Flanged Fittings; MSS SP-42, 150 lb. Corrosion Resistant Cast Flanged Valves; or API Standard 605, Large Diameter Carbon Steel Flanges. Such flanges and flanged fittings may be used for the pressure-temperature ratings given in the appropriate standard. Flanges and flanged fittings to other standards may be used, provided they have been designed in accordance with the rules of Appendix XI for the vessel design loadings and are used within the pressure-temperature ratings so determined.

(b) Where tapped holes are provided for studs, the threads shall be full and clean and shall engage the stud for a length not less than the larger of d_s or

$$0.75 d_s \times \frac{\text{Maximum allowable stress value of stud material at Design Temperature}}{\text{Maximum allowable stress value of tapped material at Design Temperature}}$$

in which d_s is the diameter of the stud. The thread engagement need not exceed $1\frac{1}{2}d_s$.

NC-3363 Access or Inspection Openings¹⁹

NC-3363.1 General Requirements

(a) All vessels for use with compressed air, except as otherwise permitted, and those subject to internal corrosion or having parts subject to erosion or mechanical abrasion shall be provided with suitable manhole, handhole, or other inspection openings for examination and cleaning.

(b) Vessels over 12 in. (305 mm) inside diameter under air pressure which also contain other substances which will prevent corrosion need not have openings for inspection only, provided the vessel contains suitable openings through which inspection can be made conveniently and provided such openings are equivalent in size and number to the requirements for inspection openings in NC-3363.3.

¹⁹ All dimensions given are nominal.

FIG. NC-3361-1 BUTT WELDING OF SECTIONS OF UNEQUAL THICKNESSES

FIG. NC-3361-1 BUTT WELDING OF SECTIONS OF UNEQUAL THICKNESSES

(c) Compressed air is not intended to include air which has had moisture removed to the degree that it has an atmospheric dew point of -50°F (-46°C) or less. The Certificate Holder's Data Report shall include a statement "for noncorrosive service" when inspection openings are not provided.

(d) When provided with telltale holes complying with the provisions of (e) below, inspection openings as required in NC-3363 may be omitted in vessels subject only to corrosion. This provision does not apply to vessels for compressed air.

(e) Telltale holes may be used to provide some positive indication when the thickness has been reduced to a dangerous degree. When telltale holes are provided, they shall be at least $\frac{3}{16}$ in. (4.8 mm) in diameter and have a depth not less than 80% of the thickness required for a seamless shell of like dimensions. These holes shall be provided in the surface opposite to that where deterioration is expected.

NC-3363.2 Requirements for Vessels 12 in. (305 mm) Inside Diameter and Smaller.

For vessels 12 in. (305 mm) or less in inside diameter, openings for inspection only may be omitted if there are at least two removable pipe connections not less than $\frac{3}{4}$ in. (19 mm) nominal pipe size.

NC-3363.3 Requirements for Vessels Over 12 in. (305 mm), but Not Over 16 in. (406 mm) Inside Diameter.

Vessels over 12 in. but not over 16 in. inside diameter, that are to be installed so that they may be disconnected from an assembly to permit inspection, need not be provided with openings for inspection only, if there are at least two removable pipe connections not less than $1\frac{1}{2}$ in. nominal pipe size (DN 40).

NC-3363.4 Equipment of Vessels Requiring Access or Inspection Openings.

Vessels that require access or inspection openings shall be equipped as required in (a) through (f) below.

(a) All vessels less than 18 in. (457 mm) and over 12 in. (305 mm) inside diameter shall have at least two handholes or two plugged, threaded inspection openings of not less than 1½ in. nominal pipe size (DN 40).

(b) All vessels 18 in. to 36 in. (457 mm to 914 mm), inclusive inside diameter, shall have a manhole or at least two handholes or two threaded pipe plug inspection openings of not less than 2 in. nominal pipe size (DN 50).

(c) All vessels over 36 in. (914 mm) inside diameter shall have a manhole, except that those whose shape or use makes one impracticable shall have at least two handholes 4 in. × 6 in. (102 mm × 152 mm) or two equal openings of equivalent area.

(d) When handholes or pipe plug openings are permitted for inspection openings in place of a manhole, one

Page 130

handhole or one pipe plug opening shall be in each head or in the shell near each head.

(e) Openings with removable heads or cover plates intended for other purposes may be used in place of the required inspection openings, provided they are equal at least to the size of the required inspection openings.

(f) A single opening with removable head or cover plate may be used in place of all the smaller inspection openings, provided it is of such size and location as to afford at least an equal view of the interior.

NC-3363.5 Size and Type of Access and Inspection Openings.

When inspection or access openings are required, they shall comply at least with the requirements of (a) and (b) below.

(a) An elliptical or obround manhole shall be not less than 11 in. × 15 in. (280 mm × 318 mm) or 10 in. × 16 in. (254 mm × 406 mm). A circular manhole shall be not less than 15 in. (381 mm) inside diameter.

(b) A handhole opening shall be not less than 2 in. × 3 in. (51 mm × 76 mm) but should be as large as is consistent with the size of the vessel and the location of the opening.

NC-3363.6 Design of Access and Inspection Openings in Shells and Heads.

All access and inspection openings in a shell or unstayed head shall be designed in accordance with the rules for openings.

NC-3363.7 Minimum Gasket Bearing Width for Manhole Cover Plates.

Manholes of the type in which the internal pressure forces the cover plate against a flat gasket shall have a minimum gasket bearing width of 1½ in.

NC-3363.8 Threaded Openings.

When a threaded opening is to be used for inspection or cleaning purposes, the closing plug or cap shall be of a material suitable for the pressure and no material shall be used at a temperature exceeding the maximum temperature allowed for that material. The thread shall be a standard taper pipe thread, except that a straight thread of equal strength may be used if other sealing means to prevent leakage are provided.

NC-3364 Attachments

Attachments used to transmit support loads shall meet the requirements of NC-3135.

NC-3365 Supports

All vessels shall be so supported and the supporting members shall be arranged or attached to the vessel wall in such a way as to withstand the maximum imposed loadings (NC-3111 and Subsection NF).

NC-3366 Bellows Expansion Joints

Expansion joints of the bellows type may be used to provide flexibility for vessels. Expansion joints in piping portions of vessels shall meet the requirements of NC-3649. The design, material, fabrication, examination, and testing of expansion joints which are constructed as a part or appurtenance of a vessel shall comply with the requirements of (a) through (i) below.

(a) Bellows may be used to absorb axial movement, lateral deflection, angular rotation, or any combination of these movements. They are not normally designed for absorbing torsion. The layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the bellows other than those for which they have been designed.

(b) In all systems containing bellows, the hydrostatic end force caused by either pressure or the bellows spring force or both shall be resisted by rigid anchors, cross connections of the expansion joint ends, or other means.

(c) The expansion joint shall be installed in such locations as to be accessible for scheduled inspection, where applicable.

(d) The joints shall be provided with bars or other suitable members for maintaining the proper face-to-face dimension during shipment and installation. Bellows shall not be extended or compressed to make up for deficiencies in length or offset to accommodate connecting parts which are not properly aligned, unless such movements have been specified by the system designer or can be justified by the expansion joint manufacturer.

(e) The expansion joints shall be marked to show the direction of flow, if applicable, and shall be installed in accordance with this marking.

(f) Internal sleeves shall be provided for expansion joints over 6 in. (152 mm) diameter when flow velocities exceed the following values:

(1) air, steam, and other gases - 25 ft/sec (7.6 m/s);

(2) water and other liquids - 10 ft/sec (3.0 m/s).

(g) Pressure retaining materials in the expansion joint shall comply with the requirements of NC-2000.

(h) All welded joints shall comply with the requirements of NC-4400.

(i) Design of bellows type expansion joints shall comply with the requirements of NC-3649.4.

Page 131

NC-3400 PUMP DESIGN

NC-3410 GENERAL REQUIREMENTS FOR CENTRIFUGAL PUMPS

NC-3411 Scope

NC-3411.1 Applicability.

The rules of NC-3400 apply to (a) through (j) below:

(a) pump casings

(b) pump inlets and outlets

(c) pump covers

(d) clamping rings

(e) seal housings, seal glands, and packing glands

(f) related bolting

(g) pump internal heat exchanger piping

(h) pump auxiliary nozzle connections up to the face of the first flange or circumferential joint in welded connections excluding the connecting weld

(i) piping identified with the pump and external to and forming part of the pressure retaining boundary and supplied with the pump

(j) external and internal integral attachments to the pressure retaining boundary

Hydrostatic test of seal glands and packing glands is not required.

[98]

NC-3411.2Exemptions.

The rules of NC-3400 do not apply to (a) through (c) below:

(a) pump shafts and impellers (shafts may be designed in accordance with Appendix S)

(b) nonstructural internals

(c) seal packages

[98]

NC-3412 Acceptability

The requirements for the design of pumps are given in (a) and (b) below.

(a) The design shall be such that the requirements of NC-3100 are satisfied.

(b) The rules of this Subarticle are met.

NC-3413 Design Specification

Design and Service Conditions (NCA-2142) shall be stipulated in the Design Specification (NCA-3250). Loads from thermal expansion, deadweight, and applicable seismic forces from the connected piping shall be included in the Design Specification.

NC-3414 Design and Service Conditions

The general design considerations, including definitions, of NC-3100 plus the requirements of NC-3320, NC-3330, NC-3361, and NC-3362 are applicable to pumps. The pump shall conform to the requirements of NC-3400. The stress limits listed in NC-3416 shall be used for the specified Design and Service Conditions. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, or any design equations, which have been demonstrated to be satisfactory, may be used.

NC-3415 Loads From Connected Piping

Loads imposed on pump inlets and outlets by connected piping shall be considered in the pump casing design.

NC-3416 Stress and Pressure Limits for Design and Service Conditions

Stress²⁰ limits for Design and Service Conditions are specified in Table NC-3416-1. The symbols used in Table NC-3416-1 are defined as follows:

σ_m

= general membrane stress, ksi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.

σ_L

= local membrane stress, ksi. This stress is the same as σ_m except that it includes the effect of discontinuities.

σ_b

= bending stress, ksi. This stress is equal to the linear varying portion of the stress across the solid section under

consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.

S

= allowable stress value, ksi, given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1. The allowable stress shall correspond to the highest metal temperature of the section under consideration during the condition under consideration.

NC-3417 Earthquake Loadings

(a) The effects of earthquake shall be considered in the design of pumps, pump supports, and restraints. The stresses resulting from these earthquake effects shall be included with the stresses resulting from pressure or other applied loads.

20 Stress means the maximum normal stress.

(b) Where pumps are provided with drivers on extended supporting structures and these structures are

Page 132

essential to maintaining pressure integrity, an analysis shall be performed when required by the Design Specifications.

**TABLE NC-3416-1
STRESS AND PRESSURE LIMITS FOR DESIGN AND SERVICE LOADINGS**

Service Limit	Stress Limits [Note (1)]	$P_{\max}$ [Note (2)]
Level A	$\sigma_m \leq S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$	1.0
Level B	$\sigma_m \leq 1.1S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$	1.1
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$	1.2
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$	1.5

NOTES:

- (1) These requirements for acceptability of pump design are not intended to assure the operability of the pump.
(2) The maximum pressure shall not exceed the tabulated factors listed under $P_{\max}$ times the Design Pressure.

TABLE NC-3416-1 STRESS AND PRESSURE LIMITS FOR DESIGN AND SERVICE LOADINGS

NC-3418 Corrosion

The requirements of NC-3121 apply.

NC-3419 Cladding

Cladding dimensions used in the design of pumps shall be required as in NC-3122.

NC-3420 DEFINITIONS

NC-3421 Radially Split Casing

A radially split casing shall be interpreted as one in which the primary sealing joint is radially disposed around the shaft.

NC-3422 Axially Split Casing

An axially split casing shall be interpreted as one in which the primary sealing joint is axially disposed with respect to the shaft.

FIG. NC-3423-1 TYPICAL SINGLE VOLUTE CASING

FIG. NC-3423-1 TYPICAL SINGLE VOLUTE CASING

NC-3423 Single and Double Volute Casings

Figures NC-3423-1 and NC-3423-2 show typical single and double volute casings, respectively.

NC-3424 Seal Housing

A seal housing is defined as that portion of the pump cover or casing assembly which contains the seal and forms a part

FIG. NC-3423-2 TYPICAL DOUBLE VOLUTE CASING

FIG. NC-3423-2 TYPICAL DOUBLE VOLUTE CASING

NC-3425 Typical Examples of Pump Types

Figures NC-3441.1-1 through NC-3441.9-2 are intended to be typical examples to aid in the determination of a pump type and are not considered as limiting. Bearing locations and inlet and outlet orientations are optional.

NC-3430 DESIGN REQUIREMENTS FOR CENTRIFUGAL PUMPS

NC-3431 Design of Welded Construction

(a) The design of welded construction shall be in accordance with NC-3350.

(b) Partial penetration welds, as shown in Fig. NC-4244(d)-1 sketch (c-3) and Fig. NC-4266(d)-1 sketches (a) and (b), are allowed for nozzles such as vent and drain connections and openings for instrumentation. Nozzles shall not exceed 2 in. nominal pipe size (DN 50). For such nozzles, all reinforcement shall be integral with the portion of the shell penetrated.

Partial penetration welds shall be of sufficient size to develop the full strength of the nozzles.

NC-3432 Flanged Connections

NC-3432.1 Pressure Design

(a) Pumps with flanged connections that are cast integrally with the casing and meet all dimensional requirements (including tolerances) of flanged fittings (as shown in Table NC-3132-1) with regard to the flange dimensions and required wall thicknesses, shall be considered to meet the pressure design requirements of this subarticle and are suitable for use within the pressure-temperature range shown in Appendix I for the material utilized.

(b) Flanged connections not meeting the requirements of (a) shall be designed in accordance with XI-3000 or L-3000.

(c) Pump flanges meeting all requirements of Table NC-3132-1 and welded onto the integral inlets and outlets of the casing, shall be considered as meeting the pressure design requirements of this subarticle, provided that the inlet and outlet wall thicknesses comply with the standard flanged fitting. However, the nozzle-to-flange welds shall meet the requirements of NC-1150.

NC-3432.2 External Loads.

When external nozzle loads interact with pumps, it is very likely that operability will dictate the maximum allowable loads. The major areas of concern are distortion of the casing and misalignment of driver and driven equipment. The casing shall be capable of withstanding the external loading plus the design pressure, provided in the Design Specification, without distortion that would impair the operation of the pump. In addition, the pump supports shall be capable of accommodating the external loads without sustaining any significant displacements that would cause unacceptable misalignment of rotating parts.

(a) Flanged connections meeting the requirements of NC-3432.1 do not require further analysis when all requirements of NC-3658.2 or NC-3658.3 are met. All other flanged connections shall all meet the requirements of NC-3432.2(b) below.

(b) Flanged connections shall meet the requirements of NC-3658.1.

NC-3433 Reinforcement of Pump Casing Inlets and Outlets

NC-3433.1 Axially Oriented Inlets and Outlets

(a) An axially oriented pump casing inlet or outlet shall be considered similar to an opening in a vessel and shall be reinforced. It shall be treated as required in NC-3330.

(b) To avoid stress concentrations, the outside radius r_2 of Figs. NC-3441.1(a)-1 and NC-3441.3-2 shall not be less than one-half the thickness of the inlets and outlets as reinforced.

NC-3433.2 Radially Oriented Inlets and Outlets.

Reinforcement of radially oriented inlets and outlets is required. The applicable portions of NC-3330 shall apply.

FIG. NC-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESS

FIG. NC-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESS

NC-3433.3 Tangential Inlets and Outlets.

Except as modified in NC-3433.4, any design method which has been demonstrated to be satisfactory for the specified Design Loadings may be used.

NC-3433.4 Minimum Tangential Inlet and Outlet Wall Thicknesses.

In Fig. NC-3433.4-1, the value of l , in., shall be determined from the relationship

$$l = 0.5\sqrt{r_m t_m}$$

where

r_m	$= r_i + 0.5t_m$, in.
r_i	$=$ maximum inlet or outlet inside radius, in.
	$= d_i/2$
t_m	$=$ mean inlet or outlet wall thickness, in., taken between section x-x and a parallel section y-y tangent to crotch radius

The wall thickness of the inlet and outlet shall not be less than the minimum wall thickness of the casing for a distance l as shown in Fig. NC-3433.4-1. The wall thickness beyond the distance l may be reduced to the minimum wall thickness of the connected piping. The change in wall thickness shall be gradual and have a maximum slope as indicated in Fig. NC-4250-1.

NC-3434 Bolting

NC-3434.1 Radially Split Configurations.

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with the procedure described in Appendix XI.

NC-3434.2 Axially Split Configurations.

Bolting in axially split configurations shall be designed in accordance with the procedure given in NC-3441.7 for Type G pumps.

NC-3435 Piping

NC-3435.1 Piping Under External Pressure.

Piping located within the pressure retaining boundary of the pump shall be designed in accordance with NC-3640.

NC-3435.2 Piping Under Internal Pressure.

Piping identified with the pump and external to or forming a part of the pressure retaining boundary, such as auxiliary water connections, shall be designed in accordance with NC-3640.

NC-3436 Attachments

(a) External and internal attachments to pumps shall be designed so as not to cause excessive localized bending stresses or harmful thermal gradients in the pump. The effects of stress concentrations shall be considered.

(b) Attachments shall meet the requirements of NC-3135.

NC-3437 Pump Covers

Pump covers shall be designed in accordance with NC-3325 or NC-3326. Covers for which specific design rules are not given in NC-3325 or NC-3326 shall be designed by any method shown by analysis or experience to be satisfactory.

NC-3438 Supports

Pump supports shall be designed in accordance with the requirements of Subsection NF, unless included under the rules of NC-3411.1(j).

FIG. NC-3441.1-1 TYPE A PUMP

FIG. NC-3441.1-1 TYPE A PUMP

FIG. NC-3441.1-2 TYPE A PUMP

FIG. NC-3441.1-2 TYPE A PUMP

NC-3440 DESIGN OF SPECIFIC PUMP TYPES

NC-3441 Standard Pump Types

NC-3441.1 Design of Type A Pumps.

Type A pumps are those having single volutes and radially split casings with a single suction as illustrated in Fig. NC-3441.1-1 and NC-3441.1-2. Pumps with nozzle sizes NPS 4 (DN 100) discharge and smaller shall be constructed in accordance with NC-3441.1(a) through NC-3441.1(e). Larger pumps are permitted as stipulated in NC-3441.1(f).

(a) *Casing Wall Thickness.* Except where specifically indicated in these rules, no portion of the casing wall shall be thinner than the value of t which is determined as follows:

$$t = (PA)/S$$

or 0.25 in., whichever is greater, where

t	= minimum allowable wall thickness, in.
P	= Design Pressure, psig
A	= scroll dimension, in., inside casing as shown in Fig. NC-3441.1(a)-1. If the value of dimension A exceeds 20 in., the formula shall not be used and (f) below applies.
S	= allowable stress, including casting factor, psi (NC-2571 and Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)

(b) *Cutwater Tip.* The cutwater tip radius shall not be less than $0.05t$.

(c) *Cutwater Fillets.* All cutwater fillets, including the tips, where they meet the casing wall, shall have a minimum radius of $0.10t$ or 0.25 in., whichever is greater.

(d) *Crotch Radius [Fig. NC-3441.1(a)-1].* The crotch radius shall not be less than $0.3t$.

(e) *Bottom of Casing.* That section of the pump casing within the diameter defined by dimension A in Fig. NC-3441.1(a)-1 on the inlet side of the casing, normally referred to as the bottom of the casing, shall have a wall thickness the greater of t from NC-3441.1(a) or t_b . The value of t_b shall be determined by methods of NC-3300 or Appendix A using the appropriate equations for the casing shape or by methods permitted in Appendix XIII.

(f) Pumps with an "A" dimension greater than 20 in. (508 mm) or nozzles larger than NPS 4 (DN 100) discharge are permitted. Design of these larger pumps must be performed in accordance with Appendix II, Experimental Stress Analysis, or Appendix XIII, Design Based on Stress Analysis for Vessels. If the design is qualified by analysis, the analysis shall be certified in accordance with NCA-3551.1.

NC-3441.2 Design of Type B Pumps.

Type B pumps are those having single volutes and radially split casings with double suction as illustrated in Fig. NC-3441.2-1. Any design method that has been demonstrated to be satisfactory for the specified design conditions may be used.

NC-3441.3 Design of Type C Pumps.

Type C pumps are those having double volutes and radially split casings with single suction as illustrated in Figs. NC-3441.3-1 and NC-3441.3-2. The splitter is considered a structural part of the casing. Their design shall be in accordance with the requirements of this Subarticle and with those given in (a) through (e) below.

(a) *Casing Wall Thickness.* Except where specifically indicated in these rules, no portion of the casing wall shall be thinner than the value of t determined as follows:

FIG. NC-3441.1(a)-1 TYPE A PUMP

FIG. NC-3441.1(a)-1 TYPE A PUMP

FIG. NC-3441.2-1 TYPE B PUMP

FIG. NC-3441.2-1 TYPE B PUMP

$$t = (0.5 PA)/S$$

FIG. NC-3441.3-1 TYPE C PUMP

FIG. NC-3441.3-1 TYPE C PUMP

where

t	= minimum allowable wall thickness, in.
P	= Design Pressure, psig
A	= scroll dimension inside casing as shown in Fig. NC-3441.3-2, in.
S	= allowable stress, including casting factor, psi (NC-2571 and Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)

(b) Splitter Wall Thickness

(1) The splitter, which is considered a structural part of the casing, shall have a minimum wall thickness of $0.7t$ as determined above for the casing wall and shall extend from point B in Fig. NC-3441.3-2 sketch (a) through a minimum angle of 135 deg. to point C.

Page 137

Beyond point C, the splitter wall may be reduced in thickness and tapered to blend with the cutwater tip radius.

FIG. NC-3441.3-2 TYPE C PUMP

FIG. NC-3441.3-2 TYPE C PUMP

(2) Cutwater tip and splitter tip radii shall not be less than $0.05t$.

(3) All cutwater and splitter fillets, including the tips, where they meet the casing wall, shall have a minimum radius of $0.10t$ or 0.25 in. (6 mm), whichever is greater.

(c) *Crotch Radius (Fig. NC-3441.3-2).* The crotch radius shall not be less than $0.3t$.

(d) *Bottom of Casing.* That section of the pump casing within the diameter defined by dimension A in Fig. NC-3441.3-2 on the inlet side of the casing, normally referred to as the bottom of the casing, shall have a wall thickness no less than the value of t determined in (a) above.

(e) *Alternative Rules for Casing Wall Thickness and Splitter Wall Thickness.* As an alternative to (a) and (b) above, it is permissible to use a smaller casing wall thickness and a larger splitter wall thickness when requirements of (1) through (3) below are met.

(1) The casing wall thickness, as determined by (a) above, shall be maintained at a minimum t , in., between the tangent point of the crotch radius to a point D radially opposite the splitter tip [Fig. NC-3441.3-2 sketch (b)]. The casing wall shall be decreased uniformly to point E from which point a minimum thickness of $0.7t$ shall be continued around the casing wall to a point on the discharge nozzle a distance l , in., from the crotch, where l is defined in Fig. NC-3433.4-1.

(2) The splitter wall thickness shall be as defined in (b) above, except that the splitter shall have a minimum thickness t , in., instead of $0.7t$.

(3) The requirements of (b)(2) and (b)(3) above shall apply.

NC-3441.4 Design of Type D Pumps

(a) Type D pumps are those having double volutes and radially split casings with double suction as illustrated in Fig. NC-3441.4(a)-1. Their design shall be in accordance with the applicable requirements of NC-3400.

(b) The requirements of NC-3441.3(a), (b), and (c), governing casing wall thickness, splitter wall thickness, and crotch radius, apply.

(c) In the casing portion between the cover and the casing wall, a wall thickness in excess of t may be required.

NC-3441.5 Design of Type E Pumps.

Type E pumps are those having volute-type radially split casings and multivane diffusers which form structural parts of the casing as illustrated in Fig. NC-3441.5-1. The design shall be in accordance with the applicable requirements of NC-3400.

FIG. NC-3441.4(a)-1 TYPE D PUMP

FIG. NC-3441.4(a)-1 TYPE D PUMP

FIG. NC-3441.5-1 TYPE E PUMP

FIG. NC-3441.5-1 TYPE E PUMP

NC-3441.6 Design of Type F Pumps

(a) Type F pumps are those having radially split, axisymmetric casings with either tangential or radial outlets as illustrated in Fig. NC-3441.6(a)-1. The basic configuration of a Type F pump casing is a shell with a dished head attached at one end and a bolting flange at the other. The outlet may be either tangent to the side or normal to the center line of the casing. Variations of these inlet and outlet locations are permitted.

FIG. NC-3441.6(a)-1 TYPE F PUMP

FIG. NC-3441.6(a)-1 TYPE F PUMP

NC-3441.7 Design of Type G Pumps²¹

(a) Type G pumps are those having axially split, single or double volute casings [Figs. NC-3441.7(a)-1 and NC-3441.7(a)-2].

(b) Manufacturers proposing this design should thoroughly review nondestructive examination requirements for compatibility.

(c) An acceptable method for calculating the stress in the most highly stressed section of the pump case, such as the section with the greatest span, is given in (1) and (2) below. This method is not acceptable for those designs in which

more than one bolt falls within a given section [Fig. NC-3441.7(c)-1, Section B-B].

(1) The following assumptions are made:

(a) assign one bolt to Section X; assign one-half bolt to Section Y, and one-half bolt to Section Z (Section Z is identical to Section Y);

(b) the flange and bolts act together in bending;

(c) the maximum moment occurs at the bolt;

(d) the total moment is distributed between the flange and case in proportion to their moments of inertia.

(2) Typical sections are shown in Figs. NC-3441.7(c)(2)-1, NC-3441.7(c)(2)-2, and NC-3441.7(c)(2)-3. The procedure for the calculation is given in (a) through (o) below.

21 It is recognized that other acceptable procedures may exist which also constitute adequate design methods, and it is not the intention to rule out these alternative methods, provided they can be shown to have been satisfactory by actual service experience.

**FIG. NC-3441.7(a)-1 AXIALLY SPLIT CASING,
VOLUTE PUMP, TYPE G**

(a) Establish the Design Pressure P , psi. Establish dimensions $A, B, C, F, R, t_c, t_p, w$, and b from Figs. NC-3441.7(c)(2)-1, NC-3441.7(c)(2)-2, and NC-3441.7(c)(2)-3 and determine the following:

A_G	= effective gasket area, sq in.
D	= diameter of bolt hole, in.
G	= $B + 0.5t_c$, in.
R	= $C - (B + t_c)$, in.
w	= section width, in.
W	= load used in calculating preliminary bolt stress, lb
W	= W_X, W_Y, W_Z
d	= bolt root diameter, in.

A_b

= bolt root area, sq in.

y	= gasket design seating stress, psi (Table XI-3221.1-1)
m	= gasket factor (Table XI-3221.1-1)
E	= modulus of elasticity of bolt at service temperature, psi
e	= unit thermal elongation of bolt, in./in./°F

DTF

= Design Temperature, °F

S_b

= allowable stress, bolt, psi

S_c

= allowable stress, case, psi

Equivalent Beam

FIG. NC-3441.7(c)(2)-3 TYPICAL LOADS ON TYPE G PUMPS

FIG. NC-3441.7(c)(2)-3 TYPICAL LOADS ON TYPE G PUMPS

(b) Determine the effective gasket area A_G sq in., for Sections X and Y :

$$A_G = \left[(A - F)w - \frac{\pi D^2}{4} \right] \times K$$

For the factor K , use 0.20 if case face is crowned for greatest contact pressure at inner edge and use 0.50 for flat surfaces.

(c) Determine bolt load, lb (N), and preliminary bolt stress σ_{PRE} , psi:

$$H = G \times w \times P$$

$$H_p = A_G \times m \times P$$

$$W_{m1} = H + H_p$$

$$W_{m2} = 0.5A_G \gamma$$

$$W = \text{greater of } W_{m1} \text{ or } W_{m2}$$

$$\sigma_{PRE} = W/A_b$$

(d) Determine the total load H_o , lb:

$$H_D = B \times w \times P$$

$$H_G = H_p$$

$$H_T = H - H_D$$

$$H_o = H_D + H_G + H_T$$

(e) Determine the lever arms h_D , h_G and h_T , in.:

$$h_D = R + 0.5t_c$$

$$h_G = h_D$$

$$h_T = 0.5(R + t_c + h_G)$$

(f) Determine the total moment M_o , in.-lb:

$$M_D = H_D h_D$$

$$M_G = H_G h_G$$

$$M_T = H_T h_T$$

$$M_o = M_D + M_G + M_T$$

(g) Determine the moments of inertia, in.⁴, I_F (flange), I_B (bolt), I_C (case), and I_T (total):

$$I_F = [w(t_f)^3/12] - [D(t_f)^3/12]$$

$$I_B = 0.049d^4$$

$$I_C = w(t_c)^3/12$$

$$I_T = I_F + I_B + I_C$$

(h) Determine the moments, in.-lb (N·mm), carried M_F (flange), M_B (bolt), and M_C (case):

$$M_F = M_o I_F / I_T$$

$$M_B = M_o I_B / I_T$$

Page 142

$$M_C = M_o I_C / I_T$$

(i) Determine the resultant bolt load F_R lb:

$$F_R = [H_D(b + h_D) + H_G(b + h_G) + H_T(b + h_T) - M_C - M_B]/b$$

or

$$F_R = H_o + [(M_o - M_C - M_B)/b]$$

(j) Determine the resultant bolt stresses, psi:

$$\sigma_{\text{Load}} = F_R / A_b$$

$$\sigma_{\text{Temp}} = eE$$

$$\sigma_{\text{Tensile}} = \sigma_{\text{Load}} + \sigma_{\text{Temp}}$$

$$\sigma_{\text{Bending}} = M_B d / 2I_B$$

(k) Determine the shear and bending flange stresses σ'_s , psi, and σ'_b , psi, respectively:

$$\sigma'_s = H_o / wt_f$$

$$\sigma'_b = M_F t_f / 2I_F$$

(l) Determine the tensile and bending case stresses σ''_t , psi, and σ''_b , psi, respectively:

$$\sigma''_t = H_D / wt_c$$

$$\sigma''_b = M_C t_c / 2I_C$$

(m) Use the following method for combining stress in combined sections.

Let F_X = load on Section X,

F_Y =load on Section Y, etc.

Let S_X =stress on Section X,

S_Y =stress on Section Y, etc.

Then the combined stress S_{COMB} is as follows:

$$S_{\text{COMB}} = (F_X + F_Y) / [(F_X/S_X) + (F_Y/S_Y)], \text{ etc.}$$

(n) Determine the maximum stresses using (1) through (4) below.

(1) To determine the preliminary bolt stress, establish the load W and the stress σ_{PRE} for Section X and for Section (Y + Z):

$$\sigma_{\text{PRE COMB}} = \frac{W_X + W_{(Y+Z)}}{\frac{W_X}{\sigma_{\text{PRE}_X}} + \frac{W_{(Y+Z)}}{\sigma_{\text{PRE}_{(Y+Z)}}}}$$

The allowable limit for this stress is S_b .

(2) To determine the resultant bolt stress, establish the load F_R and the stresses σ_t and σ_b for Section X and for Section (Y + ZF):

$$\sigma_{i\text{COMB}} = \frac{F_{R_X} + F_{R_{(Y+Z)}}}{\frac{F_{R_X}}{\sigma_{i_X}} + \frac{F_{R_{(Y+Z)}}{\sigma_{i_{(Y+Z)}}}}$$

The allowable limit for $\sigma_{i\text{COMB}}$ is $2S_b$.

$$\sigma_{b\text{COMB}} = \frac{F_{R_X} + F_{R_{(Y+Z)}}}{\frac{F_{R_X}}{\sigma_{b_X}} + \frac{F_{R_{(Y+Z)}}{\sigma_{b_{(Y+Z)}}}}$$

The allowable limit for $\sigma_{i\text{COMB}} + \sigma_{b\text{COMB}}$ is $3S_b$.

(3) To determine the flange stresses, establish the load H_o , the shear stress σ'_s , and the bending stress σ'_b for Section X and for Section $(Y+Z)$:

$$\sigma'_{s\text{ COMB}} = \frac{H_{oX} + H_{o(Y+Z)}}{\frac{H_{oX}}{\sigma'_{sX}} + \frac{H_{o(Y+Z)}}{\sigma'_{s(Y+Z)}}}$$

$$\sigma'_{b\text{ COMB}} = \frac{H_{oX} + H_{o(Y+Z)}}{\frac{H_{oX}}{\sigma'_{bX}} + \frac{H_{o(Y+Z)}}{\sigma'_{b(Y+Z)}}}$$

$$\sigma'_{s\text{ max}} = [(\sigma'_{s\text{ COMB}})^2 + (\sigma'_{b\text{ COMB}}/2)^2]^{1/2}$$

$$\sigma'_{n\text{ max}} = \sigma'_{s\text{ max}} + (\sigma'_{b\text{ COMB}}/2)$$

where $\sigma'_{n_{\max}}$ is the maximum normal stress. The allowable limit for $\sigma'_{s_{\max}}$ is S_c and the allowable limit for $\sigma'_{n_{\max}}$ is $1.5S_c$.

TEXT

Page 143

**FIG. NC-3441.8-1 LONGITUDINAL SECTION
THROUGH TYPE H PUMP**

FIG. NC-3441.8-1 LONGITUDINAL SECTION THROUGH TYPE H PUMP

(4) To determine the case stresses, establish the load H_D , the tensile stress σ_t'' , and the bending stress σ_b'' for Section X and for Section $(Y+Z)$:

$$\sigma_t''_{\text{COMB}} = \frac{H_{D_X} + H_{D_{(Y+Z)}}}{\frac{H_{D_X}}{\sigma_t''_X} + \frac{H_{D_{(Y+Z)}}{\sigma_t''_{(Y+Z)}}}$$

$$\sigma_b''_{\text{COMB}} = \frac{H_{D_X} + H_{D_{(Y+Z)}}}{\frac{H_{D_X}}{\sigma_b''_X} + \frac{H_{D_{(Y+Z)}}{\sigma_b''_{(Y+Z)}}}$$

The allowable limit for $\sigma_t''_{\text{COMB}}$ is S_c . The total stress is $\sigma_t''_{\text{COMB}} + \sigma_b''_{\text{COMB}}$. The allowable limit for total stress is $1.5S_c$.

TEXT

(o) The above procedure will generally show some bolt stresses in excess of the indicated allowable values. Under these circumstances it is permissible to average bolt stresses between adjacent bolts. Such averaged stresses shall not exceed the specified allowables.

NC-3441.8 Design of Type H Pumps.

Type H pumps are those having axially split, barrel-type casings (Figs. NC-3441.8-1 and NC-3441.8-2) and radially split covers. The axially split casing shall be designed in accordance with the rules of NC-3441.7 for Type G pumps. The radially split cover shall be designed in accordance with the rules of NC-3437.

NC-3441.9 Design of Type K Pumps.

Type K pumps are vertical pumps of one or more stages having a radially split casing as illustrated in Figs. NC-3441.9-1 and NC-3441.9-2. The basic configuration is a casing consisting of a barrel and a head joined by bolted flanges and an inner assembly consisting of internal chambers of the head, one or more bowls and columns, and a suction bell, all joined by flanges and arranged so that the external surfaces of these parts are subjected to inlet pressure. These pumps may be furnished with or without column(s) and with or without lateral restraints between the inner assembly and outer casing.

**FIG. NC-3441.8-2 TRANSVERSE SECTION
THROUGH TYPE H PUMP**

FIG. NC-3441.8-2 TRANSVERSE SECTION THROUGH TYPE H PUMP

(a) *Casing.* The barrel and head of the casing shall be designed in accordance with the requirements of NC-3400 and with those given in (1) through (3) below.

(1) *Barrel.* The Design Pressure for the barrel shall be the pump inlet pressure or as otherwise stated in the Design Specification (NCA-3250), but in no case shall it be less than the maximum pressure at the pump inlet under any Service Condition. The static head shall be considered in the selection of the Design Pressure.

(2) *Head*

(a) The external walls of the head, which form the pressure containing boundary to the atmosphere, shall be designed for the pressures specified in (b) and (c) below. The Design Pressure for the internal chambers shall be as specified under the inner assembly rules.

(b) The Design Pressure for the portions of the head that form the pressure containing boundary between the outlet pressure and the atmosphere shall be the outlet pressure or as otherwise stated in the Design Specification, but in no case shall it be less than the

Page 144

maximum pressure at the pump outlet under any Service Condition.

FIG. NC-3441.9-1 TYPE K PUMP

FIG. NC-3441.9-1 TYPE K PUMP

FIG. NC-3441.9-2 TYPE K PUMP

FIG. NC-3441.9-2 TYPE K PUMP

(c) The Design Pressure for the portions of the head that form the pressure containing boundary between the inlet pressure and the atmosphere shall be the inlet pressure or as otherwise stated in the Design Specification, but in no case shall it be less than the maximum pressure at the pump inlet under any Service Condition.

(3) *Flanged Joints, Other Than Inlets and Outlets.* Flanged joints shall be designed in accordance with Appendix XI. Class FF flanges which utilize full face gaskets are allowed, provided that allowance for gasket compression is included in calculations of the bolt load W and the flange thickness t .

(b) *Inner Assembly.* The inner assembly consists of internal chambers of the head, the bowls and columns, and the upper flange of the suction bell. It comprises those elements of the pump subjected to differential pressure within the pump and those which do not form part of the pressure boundary to the atmosphere. Design rules are under development. Until they are available, the design shall be by analysis or any procedure which can be shown to have been satisfactory by actual service experience. However, their design shall meet the rules of NC-3400 and the rules given in (1) and (2) below.

(1) *Columns and Internal Chambers of the Head.* The Design Pressure for columns and internal chambers of the head shall be not less than the maximum differential pressure which can be developed across the wall of that column or chamber under any Service Condition.

(2) *Bowls and Suction Bell*

(a) The Design Pressure for the bowl(s) shall be not less than the maximum differential pressure to which each respective bowl may be subjected under any Service Condition. Potential for interchangeability of bowls of different design ratings shall be taken into consideration.

(b) The Design Pressure for the upper flange of the suction bell (section above line A-A in Figs. NC-3441.9-1 and NC-3441.9-2) shall be not less than the maximum pressure differential developed by the first stage of the pump under any Service Condition. The remaining portion of the bell is not considered to be subject to pressure loads.

(c) Each bowl and suction bell shall be manufactured of material meeting the rules of NC-2190 and designed using the casting quality factors listed in Note (4) of Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

NC-3442 Special Pump Types

NC-3442.1 Design of Type J Pumps (Centrifugal)

(a) Type J pumps are those that cannot logically be classified with any of the preceding types of centrifugal pumps.

(b) It is not planned to establish rules for Type J pumps. Any design method which has been demonstrated to be satisfactory for the specified Design Conditions may be used.

NC-3442.2 Design of Reciprocating Pumps.

See NC-3450.

NC-3450 DESIGN OF CLASS 2 RECIPROCATING PUMPS

NC-3451 Scope

(a) These rules cover the strength and pressure integrity of the structural parts of the liquid end [Fig. NC-3451(a)-1], whose failure would violate the pressure boundary. Such parts include:

- (1) liquid cylinder and valve chambers
- (2) valve covers
- (3) liquid cylinder heads

- (4) stuffing boxes
- (5) packing glands
- (6) manifolds
- (7) piping and nozzles normally identified with the pump and furnished by the pump supplier
- (8) related bolting
- (9) external and internal integral attachments to the pressure retaining boundary

(b) These rules do not apply to the plunger or piston, nonstructural internals, including valves, valve seats, gaskets, packing, and cylinder mounting bolting. Hydrostatic testing of packing glands is not required.

NC-3452 Acceptability

The pressure boundary parts shall be capable of withstanding the specified Design Pressures, and the design shall be such that the requirements of NC-3100 are satisfied in addition to these rules.

NC-3453 Material and Stresses

Material and allowable stresses shall conform to the requirements of NC-2000.

Page 147

Page 148

FIG. NC-3451(a)-1 HORIZONTAL SINGLE-ACTING POWER PUMP LIQUID ENDS

FIG. NC-3451(a)-1 HORIZONTAL SINGLE-ACTING POWER PUMP LIQUID ENDS

NC-3454 Design Requirements

NC-3454.1 Design of Welded Construction

(a) Design of welded construction shall be in accordance with NC-3350.

(b) Partial penetration welds, as shown in Fig. NC-4244(e)-1 sketch (c-3) and Fig. NC-4266(d)-1 sketches (a) and (b), are allowed for nozzles such as vent and drain connections and openings for instrumentation. Nozzles shall not exceed 2 in. nominal pipe size (DN 50). For such nozzles, all reinforcement shall be integral with the portion of the shell penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the nozzles.

NC-3454.2 Piping.

Piping located within the pressure retaining boundary of the pump, and identified with the pump, shall be designed in accordance with NC-3600.

NC-3454.3 Liquid End.

Any design method which has been demonstrated to be satisfactory for the specified design may be used.

NC-3454.4 Fatigue.

The liquid cylinder and pressure retaining bolting are exposed to significant fatigue loadings which shall be considered in the design. Any design method which has been demonstrated to be satisfactory for the specified design may be used.

NC-3454.5 Earthquake Loadings.

The effects of earthquake shall be considered in the design of pumps. The stresses resulting from these earthquake effects shall be included with the stresses resulting from pressure or other applied loads.

NC-3454.6 Corrosion.

In designs where corrosion of material is a factor, allowances shall be made.

NC-3454.7 Bolting.

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with the procedure described in Appendix XI.

NC-3500 VALVE DESIGN

NC-3510 GENERAL REQUIREMENTS

22 CAUTIONARY NOTE: Certain types of double seated valves have the capability of trapping liquid in the body or bonnet cavity in the closed position. If such a cavity accumulates liquid and is in the closed position at a time when adjacent system piping is increasing in temperature, a substantial and uncontrolled increase in pressure in the body or bonnet cavity may result. Where such a condition is possible, it is the responsibility of the Owner or his designee to provide, or require to be provided, protection against harmful overpressure in such valves.

NC-3511 Design Specification²²

Design and Service Conditions (NCA-2142) shall be stipulated in the Design Specification (NCA-3250). The requirements of NCA-3254(a) for specifying the location of valve boundary jurisdiction may be considered to have been met by employing the minimum limits of NC-1131, unless the Design Specification extends the boundary of jurisdiction beyond these minimum limits. The requirements of NCA-3254(b) for specifying the boundary conditions are not applicable to valve end connections.

NC-3512 Standard Design Rules

NC-3512.1 Flanged and Butt Welded End Valves.

The design of valves with flanged and butt welded ends shall conform to the applicable requirements for Standard Class category valves of ANSI B16.34, except as provided in (a) and (b) below.

(a) Valves with flanged and butt welded ends may be designated as Class 75 in sizes larger than 24 in. nominal pipe size (DN 600), provided that the following additional requirements are met.

(1) The maximum rated pressure shall be 75 psi (517 kPa) for fluid temperatures from -20°F to 350°F (-29°C to 179°C).

(2) The minimum valve body wall thickness, exclusive of corrosion allowance, shall be in accordance with the following:

$$t_m = 0.4t_o + 0.2 \text{ for } d \leq 50 \text{ in.}$$

or

$$t_m = 0.008d + 0.2 \text{ for } d > 50 \text{ in.}$$

where

t_m = minimum body wall thickness, in.

t_o = minimum body wall thickness as tabulated in ANSI B16.34 for Class 150, in.

d = inside diameter, in.

(3) Flanges shall be designed in accordance with the requirements of Appendix XI, AWWA-C207 Class E, MSS-SP-44, or API-605.

(4) The minimum hydrostatic shell test pressure shall be 125 psi (861 kPa) and shall be maintained for a minimum of 10 min.

(5) The minimum valve closure test pressure shall be 85 psi (586 kPa) and shall be maintained for a minimum of 10 min.

Page 149

(b) Valves with flanged ends in sizes larger than 24 in. nominal pipe size (DN 600) may be used, provided that the following additional requirements are met.

(1) For MSS-SP-44, the Pressure Class shall be limited to Class 600 and lower, and for API-605, the Pressure Class shall be limited to Class 150 and Class 300.

(2) The operating temperatures shall be limited to the range of -20°F to 650°F (-29°C to 343°C).

(3) Flanges are designed in accordance with the requirements of Appendix XI, MSS-SP-44, or API-605.

NC-3512.2 Socket Welded End and Nonwelded End Valves.

The design of valves with socket welded end connections and nonwelded piping end connections other than ANSI B16.5 flanges shall conform to the applicable requirements for Standard Class category butt welding and valves of ANSI B16.34, except that the end connections shall conform to the applicable requirements of NC-3661 or NC-3671.

NC-3512.3 Wafer or Flangeless Valves.

The design of valves that can be bolted between flanges (i.e., butterfly valves) shall conform to the applicable requirements of Standard Class category valves of ANSI B16.34 and the requirements of (a) through (e) below.

(a) The design shall provide for bolt-up using all of the bolt holes and the bolt circle of the specified flange.

(b) Bolt holes parallel to the body run may be either threaded or unthreaded. Threaded holes may be blind holes suitable for use with bolt studs.

(c) The required minimum valve body wall thickness shall be measured from the valve inside circumference to either the valve outside circumference or the circumference of a circle inscribed about the inner tangents to the bolt holes, whichever is smaller.

(d) The inner ligament of either a through hole or a blind threaded hole in the vicinity of a stem penetration shall not be less than 25% of the required body neck thickness.

(e) The inner ligament for singular holes parallel to the body run shall not be less than 25% of the required valve body wall thickness. Such holes shall not be larger than $\frac{3}{8}$ in. diameter.

NC-3512.4 Design and Service Loadings.

The design requirements of NC-3512.1 and NC-3512.2 include pressure-temperature ratings for Design Loadings and Service Loadings for which Level A Limits are designated. When any Service Loadings are stipulated for which Level B, Level C, or Level D Limits are designated in the Design Specification, the requirements of NC-3520 shall be met.

NC-3512.5 Openings for Auxiliary Connections.

Openings for auxiliary connections, such as for drains, bypasses, and vents, shall meet the requirements of ANSI B16.34 and the applicable requirements of NC-3330.

NC-3513 Alternative Design Rules

For butt welding end valves and for socket welding end valves whose end connections conform to the requirements of NC-3661, the design requirements for Special Class category valves of ANSI B16.34 may be used in place of NC-3512 when permitted by the Design Specification, provided that the following requirements are met.

(a) The nondestructive examination requirements of ANSI B16.34, Special Class, shall be met for all sizes of butt welding and socket welding end valves in accordance with the examination methods and acceptance standards of NC-2500.

(b) When any Service Loadings are stipulated for which Level B, Level C, or Level D Limits are designated in the Design Specification, the requirements of NC-3520 shall be met.

(c) Openings for auxiliary connections, such as for drains, bypasses, and vents, shall meet the requirements of ANSI B16.34 and the applicable reinforcement requirements of NC-3330.

NC-3515 Acceptability of Metal Bellows and Metal Diaphragm Stem Sealed Valves

Valves using metal bellows or metal diaphragm stem seals shall be constructed in accordance with the rules of this Subarticle, based on the assumption that the bellows or diaphragms do not retain pressure and Design Pressure is imposed on a required backup stem seal such as packing. The bellows or diaphragms need not be constructed in accordance with the requirements of this Section.

NC-3516 Acceptability of Elastomer Diaphragm Valves

Valves using elastomer diaphragms, wherein the diaphragm performs the function of a disc or plug, shall be constructed in accordance with NC-3500. This is based on the assumptions that the diaphragms do not retain pressure, design pressure is imposed on the backup stem seal, and the additional requirements below.

(a) Design temperature shall not exceed 350°F.

Page 150

(b) Valve size and Pressure Class shall not exceed NPS 12 (DN 300) for Class 150 and NPS 4 (DN 100) for Class 300.

(c) A backup seal stem shall be provided.

(d) Diaphragms shall meet the requirements of MSS SP-100.

NC-3520 LEVEL B, C, AND D SERVICE LIMITS

NC-3521 Design Requirements

(a) When the piping system in which the valve is located is designed to the requirements of NC-3600, the valve body is considered adequate to withstand piping end loads, provided that conditions (1) and (2) below are satisfied. In lieu of (1) and (2), the design procedure of NB-3545.2 is acceptable.

(1) The section modulus and metal area at a plane normal to the flow passage through the region at the valve body crotch, that is, in the plane A-A of Fig. NC-3521-1, shall be not less than 110% of the section modulus and metal area of the piping connected to the valve body inlet and outlet nozzles.

(2) The allowable stress for valve body material is equal to or greater than the allowable stress of the connected piping material. If the valve body material allowable stress is less than that of the connected piping material, the valve section modulus and metal area shall be not less than 110% of the section modulus and metal area of the connected piping multiplied by the ratio $S_{\text{pipe}}/S_{\text{valve}}$.

(b) The maximum internal pressure resulting from Service Loadings for which Level A, Level B, Level C, or Level D limits are designated shall not exceed the tabulated factors in Table NC-3521-1 times the Design Pressure or the rated pressure at the applicable service temperature. If these pressure limits are met, loadings for the stress limits in Table NC-3521-1 are considered to be satisfied.

(c) Where valves are provided with operators having extended structures and these structures are essential to maintaining pressure integrity, an analysis, when required by the Design Specification, shall be performed based on static forces resulting from equivalent earthquake accelerations acting at the centers of gravity of the extended masses. The valve bodies shall conform to the stress limits listed in NC-3522. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, may be used.

NC-3522 Stress and Pressure Limits

Stress limits for service loadings are specified in Table NC-3521-1. The symbols used in Table NC-3521-1 are defined as follows:

σ_m	= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, psi. This stress is the same as σ_m except that it includes the effect of discontinuities.
σ_b	= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
S	= allowable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

NC-3530 GENERAL RULES

NC-3531 Hydrostatic Tests

The following requirements apply to valves designated to either NC-3512 or NC-3513.

NC-3531.1 Shell Hydrostatic Test.

A shell hydrostatic test shall be made using either water or air in accordance with the requirements of ANSI B16.34. Stem seal leakage during this test is permissible. Hydrostatic tests for metal bellows of metal diaphragm stem sealed valves shall include hydrostatic testing of the valve body, bonnet, body-to-bonnet joint, and either the bellows or diaphragm or the required backup stem seal. End closure seals for retaining fluid at test pressure in welding end valves may be positioned in the welding end transitions as defined in ANSI B16.34 in reasonable proximity to the end plane of the valve so as to ensure safe application of the test pressure.

NC-3531.2 Valve Closure.

After the shell hydrostatic test, a valve closure test shall be performed in accordance with ANSI B16.34, except that all valve sizes shall be subjected to a test differential pressure across the valve disk not less than 110% of the 100°F (38°C) pressure rating. During this test, seat leakage value is defined by the Design Specification.

Page 151

Page 152

FIG. NC-3521-1 TYPICAL SECTIONS OF VALVE BODIES

FIG. NC-3521-1 TYPICAL SECTIONS OF VALVE BODIES

**TABLE NC-3521-1
LEVEL A, B, C, AND D SERVICE LIMITS**

Service Limit	Stress Limits [Notes (1)–(4)]	$P_{\max}$ [Note (5)]
Level A	$\sigma_m \leq S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$	1.0
Level B	$\sigma_m \leq 1.1S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$	1.1
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$	1.2
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$	1.5

NOTES:

- (1) A casting quality factor of 1 shall be assumed in satisfying these stress limits.
- (2) These requirements for the acceptability of valve design are not intended to assure the functional adequacy of the valve.
- (3) Design requirements listed in this Table are not applicable to valve disks, stems, seat rings, or other parts of the valves which are contained within the confines of the body and bonnet.
- (4) These rules do not apply to safety relief valves.
- (5) The maximum pressure shall not exceed the tabulated factors listed under $P_{\max}$ times the Design Pressure or times the rated pressure at the applicable service temperature.

TABLE NC-3521-1 LEVEL A, B, C, AND D SERVICE LIMITS

NC-3531.3 Time at Pressure.

The duration of the shell hydrostatic test shall meet the requirements of NC-6223. The duration of the valve closure test shall be the greater of either 1 min/in. of minimum wall thickness t_m or the testing time requirement of ANSI B16.34, but not less than 1 min.

NC-3531.4 Exemptions to the Valve Closure Test

(a) For valves that are designed for Service Conditions that have the pressure differential across the closure member limited to values less than the 100°F pressure rating, or that have closure members or actuating devices (direct, mechanical, fluid, or electrical) that would be subject to damage at high differential pressures, the test pressure may be reduced to 110% of the maximum specified differential pressure in the closed position. This exception shall be identified in the Design Specification, and this maximum specified differential pressure shall be noted on the valve nameplate and the N Certificate Holder's Data Report Form.

(b) For valves designed for nonisolation service, the primary function of which is to modulate flow, and which by their design are prevented from providing full closure, the valve closure test defined in NC-3531.2 is not required. This exception shall be identified in the Design Specification and noted on the valve nameplate and the N Certificate Holder's Data Report Form.

NC-3590

NC-3590 PRESSURE RELIEF VALVE DESIGN

NC-3591 Acceptability

NC-3591.1 General.

The rules of this Subsubarticle constitute the requirements for the design acceptability of spring loaded pressure relief valves. The design rules for pilot operated and power actuated pressure relief valves are covered by NC-3500. The rules of this Subsubarticle cover the pressure retaining integrity of the valve inlet and outlet connections, nozzle, disk, body structure, bonnet (yoke), and body-to-bonnet (yoke) bolting. The rules of this Subsubarticle also cover other items such as the spring, spindle (stem), spring washers, and set pressure adjusting screw. The rules of this Subsubarticle do not apply to guides, control rings, bearings, set screws, and other nonpressure-retaining items. Figures NC-3591.1-1 and NC-3591.1-2 are illustrations of typical pressure relief valves.

NC-3591.2 Definitions.

The definitions for pressure relief valve terms used in this Subsubarticle are given in the American National Standard ANSI B95.1-1977, Terminology for Pressure Relief Devices, and also in NC-7000. Pressure relief valves characteristically have multipressure zones within the valve, that is, a primary

Page 153

pressure zone and a secondary pressure zone as illustrated by Figs. NC-3591.1-1 and NC-3591.1-2.

FIG. NC-3591.1-1 TYPICAL PRESSURE RELIEF DEVICES

FIG. NC-3591.1-1 TYPICAL PRESSURE RELIEF DEVICES

FIG. NC-3591.1-2 TYPICAL PRESSURE RELIEF DEVICES

FIG. NC-3591.1-2 TYPICAL PRESSURE RELIEF DEVICES

NC-3591.3 Acceptability of Small Pressure Relief Valves.

Pressure relief valves having inlet piping connections 2 in. NPS and under shall comply with the wall thickness requirements of NC-3595.1. Other elements of the valve shall be designed to ensure pressure integrity, in accordance with appropriate design practices based on successful experience in comparable service conditions.

NC-3591.4 Acceptability of Large Pressure Relief Valves.

The design shall be such that the requirements of this Subsubarticle are met.

NC-3592 Design Considerations

NC-3592.1 Design Conditions.

The general design requirements of NC-3100 are applicable, with consideration for the design conditions of the primary and secondary pressure zones. In case of conflict between NC-3100 and NC-3590, the requirements of NC-3590 shall apply. Mechanical loads for both the closed and open (full discharge) positions shall be considered in conjunction with the service conditions. In addition, the requirements of NC-7000 shall be met.

NC-3592.2 Stress Limits for Specified Service Loadings

(a) *Level A Service Loadings.* Stress limits for Level A service loadings for the valve shall be as follows.

- (1) The general membrane stress shall not exceed S .
- (2) The general membrane stress plus bending stress shall not exceed $1.5S$.
- (3) Substantiation by analysis of localized stresses associated with contact loading of bearing or seating surfaces is not required.
- (4) The values of S shall be in accordance with Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(b) *Level B, C, and D Service Loadings.* Stress limits for Level B, C, and D service loadings are specified in Table NC-3592.2(b)-1. The symbols used in Table NC-3592.2(b)-1 are defined in NC-3522.

NC-3593 Special Rules

NC-3593.1 Hydrostatic Test.

Pressure relief valve shell hydrostatic tests shall be made in accordance with NC-3531.1 and NC-3531.3 except that the inlet (primary pressure containing) portion of the pressure relief valve shall be shell tested at a pressure at least equal to 1.5 times the set pressure marked on the valve. For closed system application, the outlet portion of the pressure relief valve shall be shell tested to 1.5 times the design secondary pressure (NC-7111).

**TABLE NC-3592.2(b)-1
CLASS 2 PRESSURE RELIEF DEVICES:
LEVEL B, C, AND D SERVICE LOADINGS**

Service Loadings	Stress Limits
Level B	$\sigma_m \leq 1.1S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$

GENERAL NOTES:

- (a) A casting quality factor is not required to satisfy these limits.
- (b) These requirements for the acceptability of valve design are not intended to ensure the functional adequacy of the valve. However, the designer is cautioned that the requirements of NC-7000 relative to set pressure, lift, blowdown, and closure shall be met.
- (c) Design requirements listed in this Table are applicable to those portions of the valves which are pressure retaining or affect pressure retaining items of these valves.

TABLE NC-3592.2(b)-1 CLASS 2 PRESSURE RELIEF DEVICES: LEVEL B, C, AND D SERVICE LOADINGS

NC-3593.2 Marking.

In addition to marking required by NCA-8220 and NC-7000, the secondary Design Pressure shall be marked on the valve or valve nameplate.

NC-3594 Design Requirements for Level B, C, and D Service Loadings

(a) When the piping system in which the valve is located is designed to the requirements of NC-3600, the valve body may be considered adequate to withstand piping end loads, provided that conditions (1) and (2) below are satisfied.

(1) The section modulus and metal area at a plane normal to the flow passage through the region at the valve inlet and outlet (Figs. NC-3591.1-1 and NC-3591.1-2) shall be not less than 110% of the section modulus and metal area of the piping connected (or joined) to the valve inlet and outlet.

(2) The allowable stress for valve body material shall be equal to or greater than the allowable stress of the connected piping material. If the valve body material allowable stress is less than that of the connected piping material, the valve section modulus and metal area shall be not less than 110% of the section modulus and metal area of the connecting pipe multiplied by the ratio $S_{\text{pipe}}/S_{\text{valve}}$.

(b) The pressure retaining portions of pressure relief valves shall conform to the stress limits listed in Table NC-3592.2(b)-1

Page 156

for those Service Loadings stipulated as level B, C, or D.

(c) Pressure relief valves have extended structures, and these structures are essential to maintaining pressure integrity. An analysis, when required by the Design Specification, shall be performed based on static forces resulting from equivalent earthquake accelerations acting at the centers of gravity of the extended masses. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, may be used.

NC-3595 Design of Pressure Relief Valve Parts

NC-3595.1 Body.

Minimum wall thicknesses of valve bodies shall conform to the applicable requirements for Standard Class category valves of ANSI B16.34, taking into account the dimensional and pressure conditions of the primary and secondary zones. Minimum wall thickness adjacent to the inlet nozzle and for a distance equal to that minimum wall thickness from the plane of the back face of the inlet flange shall be that required for Standard Class category valves of ANSI B16.34 for the inlet flange size and pressure class. Minimum wall thicknesses elsewhere in the secondary zone shall be determined by the requirements for Standard Class category valves of ANSI B16.34 for the outlet flange size and pressure class, including such other rules and considerations of ANSI B16.34 as may be applicable. In valve design where the outlet flange is an extension of the bonnet, the bonnet design shall conform to these rules. Where the inlet flange geometry involves inside contours encroaching on the metal section boundary represented by dimension B in Tables 9, 12, 15, 18, 21, 24, or 27 in ANSI B16.5, adequacy of the design shall be proven by stress calculation in accordance with NC-3658. Additional metal thickness needed for operating stresses, shapes other than circular, stress concentrations, and adequate structural strength of the crotch area of the neck of the valve for bending stresses and installation stress that may be imposed on the valve must be determined by the manufacturer.

NC-3595.2 Bonnet (Yoke).

The bonnet (yoke) may be analyzed using classic bending and direct stress formulae, with appropriate free body diagrams. The general membrane stress and the general membrane stress plus bending stress shall not exceed the stress limits of NC-3592.2.

NC-3595.3 Nozzle.

The minimum wall thickness of the nozzle shall be determined from the limit on general membrane stress. Alternatively, the rules of NB-3594.3 may be used. These requirements are not applicable to the transition region to the seat contacting area of the nozzle defined by L in Fig. NC-3595.3-1, provided the dimension L is less than the nominal wall thickness t .

t = nozzle wall thickness, in.
 L = length of seal transition region, in.
 $L \leq t$

FIG. NC-3595.3-1 VALVE NOZZLE

NC-3595.4 Body-to-Bonnet Joint.

For valves having inlet piping connections 2 in. nominal pipe size (DN 50) and less, body-to-bonnet connections may be threaded. The thread shear stress, considering all loadings, shall not exceed 0.6 times the allowable stress S . The body-to-bonnet bolting shall be designed to resist the hydrostatic end force of the rated maximum secondary Design Pressure combined with the total spring load to full lift, and to maintain sufficient compression for a tight joint on the gasket or joint contact surface. The bolt stresses for these loadings shall not exceed the allowable stress values of Table 3, Section II, Part D, Subpart 1.

NC-3595.5 Disk.

The stress evaluation shall be made for the condition which results in the maximum stress in the disk. The bending stress shall not exceed the stress limits of NC-3592.2.

NC-3595.6 Spring Washer.

The shear stress shall not exceed $0.6S$. The bending stress shall not exceed the stress limits of NC-3592.2.

NC-3595.7 Spindle (Stem).

The general membrane stress shall not exceed the stress limits of NC-3592.2.

NC-3595.8 Adjusting Screw.

The adjusting screw shall be analyzed for thread stress in accordance with the method of ANSI B1.1, and this stress shall not exceed $0.6S$. The general membrane stress of the adjusting screw shall not exceed the stress limits of NC-3592.2, based on the root diameter of the thread.

NC-3595.9 Spring.

The valve spring shall be designed so that the full lift spring compression shall be no greater than 80% of the nominal solid deflection. The permanent set of the spring (defined as the difference between the free height and the height measured a minimum of 10 min after the spring has been compressed solid three additional times after presetting at room temperature) shall not exceed 1.0% of the free height.

NC-3596 Design Reports

NC-3596.1 General Requirements.

The manufacturer shall certify compliance with the requirements of this Subsubarticle in accordance with the provisions of NCA-3570.

NC-3600 PIPING DESIGN

NC-3610 GENERAL REQUIREMENTS

NC-3611 Acceptability

The requirements for acceptability of a piping system are given in the following subparagraphs.

NC-3611.1 Allowable Stress Values.

Allowable stress values to be used for the design of piping systems are given in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3.

NC-3611.2 Stress Limits

(a) *Design and Service.* Loadings shall be specified in the Design Specification.

(b) *Design Loadings.* The sum of stresses due to design internal pressure, weight, and other sustained loads shall meet the requirements of Eq. (8), NC-3652.

**TABLE NC-3611.2(e)-1
STRESS RANGE REDUCTION FACTORS**

Number of Equivalent Full Temperature Cycles <i>N</i>	<i>f</i>
7,000 and less	1.0
7,000 to 14,000	0.9
14,000 to 22,00	0.8
22,000 to 45,000	0.7
45,000 to 100,000	0.6
100,000 and over	0.5

TABLE NC-3611.2(e)-1 STRESS RANGE REDUCTION FACTORS

(c) *Service Loadings.* The following service limits shall apply to Service Loadings as designated in the Design Specifications.

(1) *Level A and B Service Limits.* For Service Loadings for which Level A and B Service Limits are designated in the Design Specification, the requirements of NC-3653 shall be met. When Level B Limits apply, the peak pressure $P_{\max}$ alone shall not exceed 1.1 times the pressure P_a calculated in accordance with Eq. (5), NC-3641.1.

(2) *Level C Service Limits.* For Service Loadings for which Level C Service Limits are designated in the Design Specification, the sum of stresses shall meet the requirements of NC-3654.

(3) *Level D Service Limits.* For Service Loadings for which Level D Service Limits are designated in the Design Specification, the sum of stresses shall meet the requirements of NC-3655.

(4) *Test Conditions.* Testing shall be in accordance with NC-6000. Occasional loads shall not be considered as acting at time of test.

(d) *External Pressure Stress.* Piping subject to external pressure shall meet the requirements of NC-3641.2.

(e) *Allowable Stress Range for Expansion Stresses.* The allowable stress range S_A is given by Eq. (1):

$$(1) S_A = f(1.25S_c + 0.25S_h)$$

where

S_c	= basic material allowable stress at minimum (cold) temperature, psi
S_h	= basic material allowable stress at maximum (hot) temperature, psi
f	= stress range reduction factor for cyclic conditions for total number N of full temperature cycles over total number of years during which system is expected to be in service from Table NC-3611.2(e)-1

Page 158

(1) In determining the basic material allowable stresses S_c and S_h , joint efficiencies need not be applied.

(2) Stress reduction factors apply essentially to noncorrosive service and to corrosion resistant materials, where employed to minimize the reduction in cyclic life caused by corrosive action.

(3) If the range of temperature change varies, equivalent full temperature cycles may be computed as follows:

$$(2) N = N_E + r_1^5 N_1 + r_2^5 N_2 + \dots + r_n^5 N_n$$

where

N_E	= number of cycles at full temperature change ΔT_E for which expansion stress S_E has been calculated
$N_1, N_2, \dots, N_n$	= number of cycles at lesser temperature changes, $\Delta T_1, \Delta T_2, \dots, \Delta T_n$
$r_1, r_2, \dots, r_n$	= $(\Delta T_1)/(\Delta T_E), (\Delta T_2)/(\Delta T_E), \dots, (\Delta T_n)/(\Delta T_E)$ = the ratio of any lesser temperature cycles for which the expansion stress S_E has been calculated

(f) *Allowable Stress for Nonrepeated Stresses.* The allowable stress due to any single nonrepeated anchor movement (e.g., predicted building settlement) calculated in accordance with Eq. (10a) of NC-3653.2(b) shall be $3.0S_c$.

NC-3612 Pressure-Temperature Ratings for Piping Products

NC-3612.1 Piping Products Having Specific Ratings

(a) Pressure-temperature ratings for certain piping products have been established and are contained in some of the standards listed in Table NC-3132-1. The pressure ratings at the corresponding temperatures given in the standards listed in Table NC-3132-1 shall not be exceeded, and piping products shall not be used at temperatures in excess of those given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 for the materials of which the products are made.

(b) Where piping products have established pressure-temperature ratings which do not extend to the upper material temperature limits permitted by this Subsection, the pressure-temperature ratings between those established and the upper material temperature limit may be determined in accordance with the rules of this Subsection.

NC-3612.2 Piping Products Not Having Specific Ratings.

Should it be desired to use methods of manufacture or design of piping products not now covered by this Subsection, it is intended that the manufacturer shall comply with the requirements of NC-3640 and NC-3690 and other applicable requirements of this Subsection for the Design Loadings involved. The manufacturer's recommended pressure ratings shall not be exceeded.

NC-3612.4 Considerations for Local Conditions and Transients

(a) Where piping systems operating at different pressures are connected by a valve or valves, the valve or valves shall be designed for the higher pressure system requirements of pressure and temperature. The lower pressure system shall be designed in accordance with (1), (2), or (3) below.

(1) The requirement of the higher pressure system shall be met.

(2) Pressure relief devices or safety valves shall be included to protect the lower pressure system in accordance with NC-7311 and NC-7321.

(3) Assure compliance with all the conditions of (a) through (e) below.

(a) Redundant check or remote actuated valves shall be used in series at the interconnection, or a check in series with a remote actuated valve.

(b) When mechanical or electrical controls are provided, redundant and diverse controls shall be installed which will prevent the interconnecting valves from opening when the pressure in the high pressure system exceeds the Design Pressure of the low pressure system.

(c) Means shall be provided such that operability of all components, controls, and interlocks can be verified by test.

(d) Means shall be provided to assure that the leakage rate of the interconnecting valves does not exceed the relieving capacity of the relief devices on the low pressure system.

(e) Adequate consideration shall be given to the control of fluid pressure caused by heating of the fluid trapped between two valves.

The low pressure system relieving capacity may be determined in accordance with NC-7311 and NC-7321, on the basis of the interconnecting valve being closed but leaking at a specified rate, when (a) through (e) above are met. The pressure relief devices or safety valves shall adjoin or be as close as possible to the interconnecting valve and shall relieve preferably to a system where the relieved effluent may be contained. The design of the overpressure protection system shall be based on pressure transients that are specified in

Page 159

the Design Specification, and all other applicable requirements of NC-7000 shall be met.

(b) When pressure reducing valves are used and one or more pressure relief devices or safety valves are provided, bypass valves may be provided around the pressure reducing valves. The combined relieving capacity of the pressure relief devices, safety valves, and relief piping shall be such that the lower pressure system service pressure will not exceed the lower pressure system Design Pressure by more than 10% if the pressure reducing valve fails in the open position and the bypass valve is open at the same time. If the pressure reducing valve and its bypass valve are mechanically or electrically interlocked so that only one may be open at any time, the high pressure system is at a pressure higher than the Design Pressure of the low pressure system, the relieving capacity of the pressure relief devices, safety valves, and relief piping shall be at least equal to the maximum capacity of the larger of the two valves. The interlocks shall be redundant and diverse.

(c) Exhaust and pump suction lines for any service and pressure shall have relief valves of a suitable size, unless the lines and attached equipment are designed for the maximum pressure and temperature to which they may be accidentally or otherwise subjected.

(d) The effluent from relief devices may be discharged outside the containment only if provisions are made for the disposal of the effluent.

(e) Drip lines from steam headers, mains, separators, or other equipment operating at different pressures shall not discharge through the same trap. Where several traps discharge into a single header that is or may be under pressure, a stop valve and a check valve shall be provided in the discharge line from each trap. The Design Pressure of trap discharge piping shall not be less than the maximum discharge pressure to which it may be subjected. Trap discharge piping shall be designed for the same pressure as the trap inlet piping, unless the discharge piping is vented to a system operated under lower pressure and has no intervening stop valves.

(f) Blowdown, dump, and drain piping from water spaces of a steam generation system shall be designed for saturated steam at the pressures and temperatures given below.

Vessel Pressure, psi	Design Pressure, psi	Design Temperature, °F
600 and below	250	410
601 to 900	400	450
901 to 1500	600	490
1501 and above	900	535

These requirements for blowdown, dump, and drain piping apply to the entire system beyond the blowdown valves to the blowdown tank or other points where the pressure is reduced to approximately atmospheric and cannot be increased by closing a valve. When pressures can be increased because of calculated pressure drop or otherwise, this shall be taken into account in the design. Such piping shall be designed for the maximum pressure to which it may be subjected.

(g) Pump discharge piping shall be designed for the maximum pressure exerted by the pump at any load and for the highest corresponding temperature actually existing.

(h) Where a fluid passes through heat exchangers in series, the Design Temperature of the piping in each section of the system shall conform to the most severe temperature condition expected to be produced by heat exchangers in that section.

NC-3613 Allowances

NC-3613.1 Corrosion or Erosion.

When corrosion or erosion is expected, the wall thickness of the piping shall be increased over that required by other design requirements. This allowance shall be consistent with the specified design life of the piping.

NC-3613.2 Threading and Grooving.

The calculated minimum thickness of piping that is to be threaded or grooved shall be increased by an allowance equal to the depth of the cut.

NC-3613.3 Mechanical Strength.

When necessary to prevent damage, collapse, or buckling of pipe due to superimposed loads from supports or other causes, the wall thickness of the pipe shall be increased, or, if this is impractical or would cause excessive local stresses, the superimposed loads or other causes shall be reduced or eliminated by other design methods.

NC-3613.4 Steel Casting Quality Factors.

The quality factors for castings required in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 apply to castings which are designed using the stresses contained in this Subsection. The minimum examination required for these castings is that stipulated in the applicable material specification and in NC-2570. Castings satisfying these minimum requirements shall be designed with a quality factor of 1.00.

Page 160

NC-3620 DESIGN CONSIDERATIONS

NC-3621 Design and Service Loadings

The provisions of NC-3110 shall apply, except as modified in this Subarticle.

NC-3621.1 Cooling Effects on Pressure.

When the cooling of a fluid may reduce the pressure in the piping to below atmospheric, the piping shall be designed to withstand the external pressure or provision shall be made to break the vacuum.

NC-3621.2 Fluid Expansion Effects.

When the expansion of a fluid may increase the pressure, the piping system shall be designed to withstand the increased pressure or provision shall be made to relieve the excess pressure.

NC-3622 Dynamic Effects

NC-3622.1 Impact.

Impact forces caused by either external or internal loads shall be considered in the piping design.

NC-3622.2 Reversing Dynamic Loads.

Reversing dynamic loads are those loads which cycle about a mean value and include building filtered loads, earthquake, and the reflected waves in a piping system due to flow transients resulting from sudden opening or closure of valves (see Fig. NC-3622-1). A reversing dynamic load shall be treated as a nonreversing dynamic load in applying the rules of NC-3600 when either of the following conditions exist:

(a) The frequency ratio of the dynamic dominant load driving frequency to the lowest piping system natural frequency is less than 0.5.

(b) The number of reversing dynamic load cycles, exclusive of earthquake, exceed 20.

NC-3622.3 Vibration.

Piping shall be arranged and supported so that vibration will be minimized. The designer shall be responsible, by design and by observation under startup or initial service conditions, for ensuring that vibration of piping systems is within acceptable levels.

NC-3622.4 Exposed Piping.

Exposed piping shall be designed to withstand wind loadings, using meteorological data to determine wind forces. When State, Province, or Municipal ordinances covering the design of building structures are in effect and specify wind loadings, these values shall be considered the minimum design values. However, it is not necessary to consider earthquake and wind loadings to be acting concurrently.

NC-3622.5 Nonreversing Dynamic Loads.

Nonreversing dynamic loads are those loads which do not cycle about a mean value and include the initial thrust force due to sudden opening or closure of valves and waterhammer resulting from entrapped water in two-phase flow systems (see Fig. NC-3622-1).

NC-3623 Weight Effects

Piping systems shall be supported to provide for the effects of live and dead weights, as defined in the following subparagraphs, and they shall be arranged or properly restrained to prevent undue strains on equipment.

NC-3623.1 Live Weight.

The live weight shall consist of the weight of the fluid being handled or of the fluid used for testing or cleaning, whichever is greater.

NC-3623.2 Dead Weight.

The dead weight shall consist of the weight of the piping, insulation, and other loads permanently imposed upon the

piping.

NC-3624 Thermal Expansion and Contraction Loads

NC-3624.1 General Requirements

(a) The design of piping systems shall take account of the forces and moments resulting from thermal expansion and contraction and from the effects of expansion joints.

(b) Thermal expansion and contraction shall be provided for, preferably by pipe bends, elbows, offsets, or changes in direction of the pipeline.

(c) Hangers and supports shall permit expansion and contraction of the piping between anchors.

NC-3624.2 Expansion Joints.

Expansion joints of the corrugated slip sleeve, ball, or swivel types may be used if they conform to the requirements of NC-3649.1 through NC-3649.7; their structural and working parts are designed for the maximum pressure and temperature of the piping system; and their design prevents the complete disengagement of working parts while in service.

NC-3640 PRESSURE DESIGN OF PIPING PRODUCTS

NC-3641 Straight Pipe

[98]

NC-3641.1 Straight Pipe Under Internal Pressure.

The minimum thickness of pipe wall required for Design Pressures and for temperatures not exceeding those for

Page 161

Page 162

the various materials listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, including allowances for mechanical strength, shall not be less than that determined by Eq. (3) as follows:

$$t_m = \frac{PD_o}{2(S + Py)} + A \quad (3)$$

$$t_m = \frac{Pd + 2SA + 2yPA}{2(S + Py - P)} \quad (4)$$

(3 - 4)

**(a) Nonreversing Dynamic Load
(Relief/Safety Valve Open End Discharge)**

**(b) Reversing Dynamic Load
(Earthquake Load Cycling About Normal Operating Condition)**

**(c) Nonreversing Followed By Reversing
(Initial Water Slug Followed By Reflected Pressure Pulses)**

FIG. NC-3622-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

FIG. NC-3622-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

where

t_m	= minimum required wall thickness, in. If pipe is ordered by its nominal wall thickness, the manufacturing tolerance on wall thickness must be taken into account. After the minimum pipe wall thickness t_m is determined by Eq. (4), this minimum thickness shall be increased by an amount sufficient to provide the manufacturing tolerance allowed in the applicable pipe specification or required by the process. The next heavier commercial wall thickness shall then be selected from standard thickness schedules such as contained in ANSI B36.10 or from manufacturers' schedules for other than standard thickness.
P	= internal Design Pressure, psi
D_o	= outside diameter of pipe, in. For design calculations, the outside diameter of pipe as given in tables of standards and specifications shall be used in obtaining the value of t_m . When calculating the allowable pressure of pipe on hand or in stock, the actual measured outside diameter and actual measured minimum wall thickness at the thinner end of the pipe may be used to calculate this pressure.
d	= inside diameter of pipe, in. In using Eq. (4) the value of d is for the maximum possible inside diameter allowable under the purchase specifications.
S	= maximum allowable stress for the material at the Design Temperature, psi (Section II, Part D, Subpart 1, Tables 1A and 1B)
A	= an additional thickness to provide for material removed in threading, corrosion or erosion allowance, and material required for structural strength of the pipe during erection, as appropriate, in.

The allowable working pressure of pipe may be determined from the following equation:

$$P_a = \frac{2St}{D_o - 2yt} \quad (5)$$

(5)

**TABLE NC-3641.1(a)-1
VALUES OF A**

Type of Pipe	A , in.
Threaded steel & nonferrous pipe:	
$\frac{3}{4}$ in. nominal & smaller	0.065
1 in. nominal & larger	Depth of Thread
Grooved steel & nonferrous pipe	Depth of Groove
	plus $\frac{1}{64}$ in.

TABLE NC-3641.1(a)-1 VALUES OF A

where

t

= the specified or actual wall thickness minus, as appropriate, material removed in threading, corrosion or erosion allowance, material manufacturing tolerances, bending allowance (NC-3642.1), and material to be removed by counterboring, in.

P_a

= the calculated maximum allowable internal pressure, psi, for straight pipe which shall at least equal the Design Pressure. P_a may be used for piping products with pressure ratings equal to that of straight pipe (see ANSI B16.9). For standard flanged joints, the rated pressure shall be used instead of P_a . For other piping products where the pressure rating may be less than that of the pipe [for example, flanged joints designed to Appendix XI and reinforced branch connections (NC-3643) where part of the required reinforcement is in the run pipe], the Design Pressure shall be used instead of P_a . P_a may be rounded out to the next higher unit of 10.

y

= a coefficient having a value of 0.4, except that, for pipe with a D_o/t_m ratio less than 6, the value of y shall be taken as

$$y = \frac{d}{d + D_o} \quad (6)$$

(6)

(a) To compensate for material removed or wall thinning due to threading, or grooving, required to make a mechanical joint. The values of A listed in Table NC-3641.1(a)-1 are minimum values for material removed in threading.

(b) To provide for mechanical strength of the pipe. Small diameter, thin wall pipe or tubing is susceptible to mechanical damage due to erection, operation, and maintenance procedures. Accordingly, appropriate means must be employed to protect such piping against

Page 163

these types of loads if they are not considered as Design Loads. Increased wall thickness is one way of contributing to resistance against mechanical damage.

**TABLE NC-3642.1(c)-1
MINIMUM THICKNESS FOR BENDING**

Radius of Bends	Minimum Thickness Recommended Prior to Bending [Note (1)]
6 pipe diameters or greater	$1.06t_m$
5 pipe diameters	$1.08t_m$
4 pipe diameters	$1.16t_m$
3 pipe diameters	$1.25t_m$

NOTE:

(1) t_m is determined by Eq. (3) or (4) of NC-3641.1.

TABLE NC-3642.1(c)-1 MINIMUM THICKNESS FOR BENDING

(c) To provide for corrosion or erosion. Since corrosion and erosion vary widely from installation to installation, it is the responsibility of designers to determine the proper amounts which must be added for either or both of these conditions.

[98]

NC-3641.2 Straight Pipe Under External Pressure.

For determining wall thickness and stiffening requirements for straight pipe under external pressure, the procedures outlined in NC-3133 shall be followed.

NC-3642 Curved Segments of Pipe

NC-3642.1 Pipe Bends.

Pipe bends shall be subject to the limitations in (a), (b), and (c) below.

(a) The minimum wall thickness after bending shall not be less than the minimum wall thickness required for straight pipe.

(b) The ovality shall meet the requirements of NC-4223.2.

(c) The information in Table NC-3642.1(c)-1 is given to guide the designer when ordering pipe.²³

NC-3642.2 Elbows.

Flanged elbows manufactured in accordance with the standards listed in Table NC-3132-1 shall be considered suitable for use at the pressure-temperature ratings specified by such standards. In the case of standards under which butt welding elbows are made to a nominal wall thickness, the elbows shall be considered suitable for use with pipe of the same nominal thickness and of the same material.

²³ The minimum thicknesses of straight pipe shown in Table NC-3642.1(c)-1 should be sufficient to allow the pipe to meet the minimum wall thickness requirements of NC-3641 after having been bent on the radii shown.

NC-3643 Intersections

[98]

NC-3643.1 General Requirements

(a) NC-3643 gives acceptable rules governing the design of branch connections to sustain internal and external pressure in cases where the axes of the branch and the run intersect, the angle between the axes of the branch and of the run is between 45 deg. and 90 deg., inclusive, and no allowance is required for corrosion or erosion.

(b) Branch connections in which the smaller angle between the axes of the branch and the run is less than 45 deg. impose special design and fabrication problems. The rules given for angles of 45 deg. and 90 deg., inclusive, may be used as a guide, but sufficient additional strength must be provided to assure safe service. Such branch connections shall be designed to meet the requirements of NC-3649.

(c) Branch connections in piping may be made by using one of the products or methods given in (1) through (4) below:

(1) flanged, butt welding, socket welding, or screwed fittings made in accordance with the applicable standards listed in Table NC-3132-1;

(2) welded outlet fittings, such as cast or forged nozzles; couplings, including ANSI B16.11 couplings, to a maximum nominal size of 3 in. (DN 80); and adaptors or similar items having butt welding, socket welding, threaded, or flanged ends for attachment of the branch pipe. Such outlet fittings shall be attached to the main pipe:

(a) by a full penetration weld; or

(b) for right angle branch connections, by a fillet weld or partial penetration weld as shown in Figs. NC-3643.2(b)-2 (e) or (f), provided the requirements of (1) through (4) below are met:

(1) the nominal size of the branch shall not exceed 2 in. or one-quarter of the nominal size of the run, whichever is less;

(2) the minimum size of the weld, $x_{\min}$, shall not be less than $1\frac{1}{4}$ times the fitting wall thickness in the reinforcement zone;

(3) the groove angle, θ , shall be equal to or greater than 45 deg.;

(4) except for attaching ANSI B16.11 couplings, the requirements of NC-3643.3 shall be met.

(3) extruded outlets at right angles to the run pipe, in accordance with NC-3643.4, where the attachment of the branch pipe is by butt welding;

(4) by attaching the branch pipe directly to the run pipe by welding or threading as stipulated in (a), (b), or (c) below:

Page 164

(a) right angle branch connections may be made by attaching the branch pipe to the run pipe by socket welding, provided the requirements of (1) through (5) below are met:

(1) the nominal size of branch does not exceed 2 in. or one-quarter the nominal size of the run, whichever is less;

(2) the depth of the socket in the run is at least equal to that shown in ANSI B16.11 with a minimum shoulder of $\frac{1}{16}$ in. (1.6 mm) between the bottom of the socket and the inside diameter of the run pipe; weld metal may be deposited on the run pipe to provide the required socket depth and to provide any reinforcement required;

(3) a minimum of $\frac{1}{16}$ in. (1.6 mm) clearance shall be provided between the bottom of the socket and the end of the inserted pipe;

(4) the size of the fillet weld shall not be less than $1\frac{1}{4}$ times the nominal branch wall thickness;

(5) the requirements of NC-3643.3 shall be met.

(b) right angle branch connections may be made by attaching the branch pipe directly to the run by threading within the provisions of NC-3671.3 and provided the requirements of (1) and (2) below are met:

(1) the nominal size of the branch does not exceed 2 in. or one-quarter of the nominal size of the run, whichever is less;

(2) minimum thread engagement shall be six full threads for $\frac{1}{2}$ in. (DN 15) and $\frac{3}{4}$ in. (DN 20) branches; seven for 1 in. (DN 25), $1\frac{1}{4}$ in. (DN 32), and $1\frac{1}{2}$ in. (DN 40) branches; and eight for 2 in. (DN 50) branches; weld metal may be deposited on the run pipe to provide sufficient thickness for required thread engagement;

(5) branch connections may be made by attaching the branch pipe directly to the run pipe:

(a) by a full penetration weld as shown in Fig. NC-3643.2(b)-1, with or without pad or saddle reinforcement as shown in Fig. NC-3643.3(c)(1)-1 or Fig. NC-3643.3(c)(1)-2, provided the requirements of NC-3643.3 are met; or

(b) for right angle branch connections, by a fillet weld or partial penetration weld as shown in Fig. NC-3643.2(b)-2, sketches (a) through (d), provided the requirements of (1) through (4) below are met:

(1) the nominal size of the branch shall not exceed 2 in. (DN 50) or one-quarter of the nominal size of the run, whichever is less;

(2) the minimum size of the weld, $x_{\min}$, shall not be less than $1\frac{1}{4}$ times the nominal branch wall thickness;

Page 165

(a) Typical Welded Branch Connection Without Additional Reinforcement

(b) Typical Welded Angular Branch Connection Without Additional Reinforcement

(c)

FIG. NC-3643.2(b)-1 TYPICAL WELDED BRANCH CONNECTIONS

FIG. NC-3643.2(b)-1 TYPICAL WELDED BRANCH CONNECTIONS

(3) the groove angle, θ , shall be equal to or greater than 45 deg.;

(4) the requirements of NC-3643.3 shall be met.

[98]

[98]

NC-3643.2 Branch Connections Not Requiring Reinforcement.

Reinforcement need not be provided if the branch connection is made in accordance with the requirements of (a) through (c) below:

(a) by the use of a fitting manufactured in accordance with one of the standards listed in Table NC-3132-1 and used within the limits of pressure-temperature ratings specified in such standard, a butt welding fitting made in accordance with ANSI B16.9 shall be of nominal thickness not less than the nominal thickness required for the adjoining pipe;

(b) by welding a coupling or half coupling directly to the run pipe, provided the nominal diameter of the branch does not exceed 2 in. pipe size (DN 50) or one-quarter the nominal diameter of the run, whichever is less; the wall thickness of the coupling is not less than that of the branch pipe; the coupling is joined to the run pipe by one of the methods shown in Fig. NC-3643.2(b)-1, sketch (c)(1) or Fig. NC-3643.2(b)-2, sketch (e); and in no case is the thickness of the coupling less than extra heavy or 3000 lb nominal rating;

(c) by using an extruded outlet, provided the nominal diameter of the branch does not exceed 2 in. pipe size (DN 50) or one-quarter of the nominal diameter of the pipe, whichever is less, and the minimum wall thickness at the abutting end of the outlet is not less than required for the branch pipe wall.

[98]

NC-3643.3 Branch Connections Requiring Reinforcement

(a) Calculations shall be made to determine the adequacy of reinforcement in branch connections, except as exempted in NC-3643.2.

(b) A branch connection may be made by extruding an integrally reinforced outlet on the run pipe. The reinforcement requirements shall be in accordance with NC-3643.4.

(c) A branch connection may be made by welding a pipe or fitting directly to the run pipe with or without added reinforcement, provided the pipe or fitting, deposited weldment, and other reinforcing devices meet the requirements of this subparagraph. This subparagraph gives rules covering the design of branch connections to sustain internal pressure in cases where the angle between the axes of the branch and of the run ranges from 45 deg. to 90 deg. NC-3643.5 gives rules governing the design of connections to sustain external pressure.

(1) *Nomenclature.* Figures NC-3643.3(c)(1)-1 and NC-3643.3(c)(1)-2 illustrate the notations used in the pressure-temperature design conditions of branch connections, which are as follows:

α	= angle between axes of branch and run, deg.
b	= subscript referring to branch
D_o	= outside diameter of pipe, in.
d_1	= inside diameter of branch for right angle connections, in.; for connections at angles between 45 deg. and 90 deg., $d_1 = (D_{ob} - 2T_b)/\sin \alpha$
d_2	= half width of reinforcing zone, in. = the greater of d_1 or $T_b + T_h + (d_1/2)$ but in no case more than D_{ob}

h	= subscript referring to run or header
L	= height of reinforcement zone outside of run or reinforcement, in. = $2.5T_b$
t_e	= thickness of attached reinforcing pad or height of the largest 60 deg. right triangle supported by the run and branch outside diameter projected surfaces and lying completely within the area of integral reinforcement, in. [Fig. NC-3643.3(c)(1)-2]
T	= nominal, actual by measurement, or minimum wall thickness of pipe, in., permissible under purchase specification
t_m	= required minimum wall thickness, in., of pipe for pressure and temperature design conditions as determined by use of Eq. (3) or (4), NC-3641.1

(2) *Requirements.* A pipe having a branch connection is weakened by the opening that must be made in it, and unless the wall thickness of the pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide additional reinforcement. The amount of reinforcement required shall be determined in accordance with NC-3643.3(c)(3) through NC-3643.3(c)(7), NC-3643.4 or NC-3643.5.

(3) *Reinforcement Area.* The required reinforcement area in sq in. for branch connections shall be the quantity $1.07(t_{mh})(d_1)(2 - \sin \alpha)$.

(a) For right angle connections, the required reinforcement becomes $1.07(t_{mh})(d_1)$.

(b) The required reinforcement must be within the limits of the reinforcement zone as defined in NC-3643.3(c)(5).

(4) *Area Contributing to Reinforcement.* Metal needed to meet reinforcement required by NC-3643.3(c) must be within the limits of the reinforcement zone determined in NC-3643.3(c)(5) and may include the following:

Page 166

Page 167

T_b = Nominal branch pipe wall thickness
 $X_{min.} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg.

T_b = Fitting wall thickness in the reinforcement zone
 (when the fitting is tapered in the reinforcement zone, use average wall thickness)
 $X_{min.} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg.

98

FIG. NC-3643.2(b)-2 TYPICAL RIGHT ANGLE BRANCH CONNECTIONS MADE USING A FILLET WELD OR A PARTIAL PENETRATION WELD

[98]

FIG. NC-3643.2(b)-2 TYPICAL RIGHT ANGLE BRANCH CONNECTIONS MADE USING A FILLET WELD OR A PARTIAL PENETRATION WELD

[98]

FIG. NC-3643.3(c)(1)-1 REINFORCEMENT OF BRANCH CONNECTIONS

A_1	= area provided by excess pipe wall in the run, sq in. $= (2d_2 - d_1) [(T_h - \text{mill tolerance on } T_h) - t_{mh}]$
A_2	= area provided by excess pipe wall in the branch for a distance L above the run, sq in. $= 2L/\sin \alpha [(T_b - \text{mill tolerance on } T_b) - t_{mb}]$. In areas A_1 and A_2 mill tolerance becomes zero when the minimum wall is specified instead of nominal wall.
A_3	= area provided by deposited weld metal beyond the outside diameter of the run and branch, sq in.
A_4	= area provided by reinforcement, sq in.

FIG. NC-3643.3(c)(1)-2 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE k_r REINFORCEMENT DIMENSIONS

FIG. NC-3643.3(c)(1)-2 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e
REINFORCEMENT DIMENSIONS

When reinforcement area is composed of material with lower allowable stress than that of the run pipe, such reinforcement areas shall be increased by the inverse ratio of allowable stresses. No adjustment shall be made in reinforcement area for use of materials that have higher allowable stresses than the materials of the run pipe. Such reinforcement areas shall be decreased by the ratio of allowable stresses prior to any combination of areas to meet the reinforcement requirements of NC-3643.3(c).

(5) *Reinforcement Zone.* The reinforcement zone is a parallelogram, the length of which shall extend a distance d_2 on each side of the center line of the branch pipe and the width of which shall start at the inside surface of the run pipe and extend to a distance $(L + t_e)$ or $2.5T_p$ whichever is less, from the outside surface of the run pipe, when measured in the plane of the branch connection.

(6) *Reinforcement of Multiple Openings*

(a) When any two or more adjacent openings are so closely spaced that their reinforcement zones overlap, the two or more openings shall be reinforced in accordance with NC-3643.3(c)(3) with a combined reinforcement that has a strength equal to the combined strength of the reinforcement which would be required for the separate openings. No portion of the cross section shall be considered as applying to more than one opening or be evaluated more than once in a combined area.

(b) When more than two adjacent openings are to be provided with a combined reinforcement, the minimum distance between centers of any two of these openings should preferably be at least $1\frac{1}{2}$ times their average diameter and the area of reinforcement between them shall be at least equal to 50% of the total required for these two openings.

(7) *Rings, Pads, and Saddles*

(a) Reinforcement provided in the form of rings, pads, or saddles shall not be appreciably narrower at the side than at the crotch.

(b) A vent hole shall be provided at the ring, pad, or saddle to provide venting during welding and heat treatment.

(c) Rings, pads, or saddles may be made in more than one piece, provided the joints between pieces have full thickness welds and each piece is provided with a vent hole.

(d) Where saddles or pads are being employed for reinforcement, the potential for increased strain at the attachment welds which may occur as a result of rapid changes in differential metal temperatures between the saddle or pad, and the run should be considered in the design evaluation.

NC-3643.4 Special Requirements for Extruded Outlets.

The definitions, limitations, nomenclature, and requirements of (a) through (h) below are specifically applicable to extruded outlets.

(a) *Definition.* An extruded outlet header is a header in which the extruded lip at the outlet has a height above the surface of the run which is equal to or greater than the radius of the curvature of the external contoured portion of the outlet, $h_o \geq r_o$ [Fig. NC-3643.4(a)-1].

(b) *Cases to Which Rules Are Applicable.* These rules apply only to cases where the axis of the outlet intersects and is perpendicular to the axis of the run.

(c) *Nomenclature.* The notation used herein is illustrated in Fig. NC-3643.4(a)-1. All dimensions are in inches.

d	= outside diameter of branch pipe, in.
d_c	= corroded internal diameter of branch pipe, in.
D	= outside diameter of run, in.

D_c	= corroded internal diameter of run, in.
D_o	= corroded internal diameter of extruded outlet measured at the level of the outside surface of the run, in.
h_o	= height of the extruded lip, in.; this must be equal to or greater than r_o except as permitted in NC-3643.4(d)(4)
L	= height of reinforcement zone, in. $= 0.7\sqrt{dT_o}$
t_b	= required thickness of branch pipe according to wall thickness Eq. (3) or (5), NC-3641.1, but not including any thickness for corrosion, in.
T_b	= actual thickness of branch wall not including corrosion allowance, in.
t_r	= required thickness of the run according to Eq. (3) or (5), NC-3641.1, but not including any allowance for corrosion, in.
T_r	= actual thickness of run wall, not including the corrosion allowance, in.
T_o	= corroded finished thickness of extruded outlet measured at a height equal to r_o above the outside surface of the run, in.

Page 170

Page 171

r_1	= half width of reinforcement zone, in. $= D_o$
r_o	= radius of curvature of external contoured portion of outlet measured in the place containing the axes of the run and branch, in.; this is subject to the limitations given in (d) below

FIG. NC-3643.4(a)-1 REINFORCED EXTRUDED OUTLETS

FIG. NC-3643.4(a)-1 REINFORCED EXTRUDED OUTLETS

(d) *Radii*

(1) The minimum radius shall not be less than $0.05d$, except that on branch diameters larger than 30 in. (762 mm) it need not exceed $1\frac{1}{2}$ in. (38 mm).

(2) The maximum radius for outlet pipe sizes 6 in. nominal and larger shall not exceed $0.10d + 0.50$ in. For outlet pipe sizes less than 6 in. nominal, this dimension shall be not greater than $1\frac{1}{4}$ in.

(3) When the external contour contains more than one radius, the radius of any arc sector of approximately 45 deg. shall meet the requirements of (1) and (2) above.

(4) Machining shall not be employed in order to meet the above requirements.

(e) *Required Area.* The required area is defined as $A = K(t_r \times D_o)$ where K shall be taken as follows:

(1) for d/D greater than 0.60, $K = 1.00$

(2) for d/D greater than 0.15 and not exceeding 0.60, $K = 0.6 + 2d/3D$

(3) for d/D equal to or less than 0.15, $K = 0.70$

(f) *Reinforcement Area.* The reinforcement area shall be the sum of areas $A_1 + A_2 + A_3$ as defined in (1), (2), and (3) below.

(1) Area A_1 is the area lying within the reinforcement zone resulting from any excess thickness available in the run wall:

$$A_1 = D_o(T_r - t_r)$$

(2) Area A_2 is the area lying within the reinforcement zone resulting from any excess thickness available in the branch pipe wall:

$$A_2 = 2L(T_b - t_b)$$

(3) Area A_3 is the area lying within the reinforcement zone resulting from excess thickness available in the extruded outlet lip:

$$A_3 = 2r_o(T_o - T_b)$$

(g) *Reinforcement of Multiple Openings.* When any two or more adjacent openings are so closely spaced that the reinforcement zones overlap, the two or more openings shall be reinforced in accordance with NC-3643.4, with a combined reinforcement that has a strength equal to the combined strength of the reinforcement that would be required for separate openings. No portion of the cross section shall be considered as applying to more than one opening or be evaluated more than once in a combined area.

(h) *Marking.* In addition to the above, the Certificate Holder shall be responsible for establishing and marking on the section containing extruded outlets, the Design Pressure and Temperature, and the Certificate Holder's name or trademark.

NC-3643.5 Branch Connections Subject to External Pressure

(a) The reinforcement area in sq in. required for branch connections subject to external pressure shall be $0.54(t_{mh})(d_1)(2 - \sin \alpha)$. See NC-3643.3(c)(1).

(b) Procedures established for connections subject to internal pressure shall apply for connections subject to external pressure.

NC-3643.6. Reinforcement of Other Designs.

The adequacy of designs to which the reinforcement requirements of NC-3643 cannot be applied shall be proved by burst or proof tests (NC-3649) on scale models or on full size structures, or by calculations previously substantiated by successful service of similar design.

NC-3644 Miters

Mitered joints may be used in piping systems under the conditions stipulated in (a) through (e) below.

(a) The thickness of a segment of a miter shall be determined in accordance with NC-3641.1. The required thickness thus determined does not allow for the discontinuity stresses which exist at the junction between segments. The discontinuity stresses are reduced for a given miter as the number of segments is increased. These discontinuity stresses may be neglected for miters in noncyclic services with incompressible fluids at pressures of 100 psi (690 kPa) and under, and for gaseous vents to atmosphere. Miters to be used in other services or at higher pressures shall meet the requirements of NC-3649.

(b) The number of full pressure or thermal cycles shall not exceed 7000 during the expected lifetime of the piping system.

(c) The angle θ in Fig. NC-3673.2(b)-1 shall not be more than $22\frac{1}{2}$ deg.

(d) The center line distance between adjacent miters shall be in accordance with Fig. NC-3673.2(b)-1.

(e) Full penetration welds shall be used in joining miter segments.

Page 172

NC-3645 Attachments

(a) External and internal attachments to piping shall be designed so as not to cause flattening of the pipe, excessive localized bending stresses, or harmful thermal gradients in the pipe wall. It is important that such attachments be designed to minimize stress concentrations in applications where the number of stress cycles, due either to pressure or thermal effect, is relatively large for the expected life of the equipment.

(b) Attachments shall meet the requirements of NC-3135.

NC-3646 Closures

(a) Closures in piping systems shall be made by use of closure fittings, such as blind flanges or threaded or welded plugs or caps, either manufactured in accordance with standards listed in Table NC-3132-1 and used within the specified pressure-temperature ratings, or made in accordance with (b) below.

(b) Closures not manufactured in accordance with the standards listed in Table NC-3132-1 may be made in accordance with the rules contained in NC-3300 of this Subsection using the equation $t_m = t + A$, where

t_m	= minimum required thickness, in.
t	= pressure design thickness, calculated for the given closure shape and direction of loading using appropriate equations and procedures in NC-3000, in.
A	= sum of mechanical allowances (NC-3613), in.

(c) Connections to closures may be made by welding, extruding, or threading. Connections to the closure shall be in accordance with the limitations provided in NC-3643 for branch connections. If the size of the opening is greater than one-half the inside diameter of the closure, the opening shall be designed as a reducer in accordance with NC-3648.

(d) Other openings in closures shall be reinforced in accordance with the requirements of reinforcement for a branch connection. The total cross-sectional area required for reinforcement in any plane passing through the center of the opening and normal to the surface of the closure shall not be less than the quantity of $d_5 t$, where

d_5	= diameter of the finished opening, in.
t	= pressure design thickness for the closure, in.

NC-3647 Pressure Design of Flanged Joints and Blanks

NC-3647.1 Flanged Joints

(a) Flanged joints manufactured in accordance with the standards listed in Table NC-3132-1, as limited by NC-3612.1, shall be considered as meeting the requirements of NC-3640.

(b) Flanged joints not included in Table NC-3132-1 shall be designed in accordance with XI-3000.

[98]

NC-3647.2 Permanent Blanks.

The minimum required thickness of permanent blanks (Fig. NC-3647.2-1) shall be calculated from the following equations:

$$t_m = t + A$$

where

t_m	= the minimum required thickness, in.
t	= the pressure design thickness calculated from the equation below, in.
A	= the sum of the mechanical allowances, in. (NC-3613)

$$t = d_6 \left(\frac{3P}{16S} \right)^{1/2}$$

where

d_6	= the inside diameter of the gasket for raised or flat face flanges or the pitch diameter of the gasket for retained gasketed flanges, in.
P	= Design Pressure, psi
S	= the allowable stress in accordance with Section II, Part D, Subpart 1, Tables 1A and 1B

[98]

[98]

NC-3647.3 Temporary Blanks.

Blanks to be used for test purposes only shall have a minimum thickness not less than the pressure design thickness t

calculated as in NC-3647.2 above, except that P shall not be less than the test pressure and the allowable stress S may be taken as 95% of the specified minimum yield strength of the blank material (Section II, Part D, Subpart 1, Table Y-1).
[98]

NC-3647.4 Flanges.

Flanges shall be integral or be attached to pipe by welding, brazing, threading, or other means within the applicable standards specified in Table NC-3132-1.

NC-3647.5 Gaskets

(a) Gaskets shall be made of materials which are not injuriously affected by the fluid or by temperatures within the design temperature range.

(b) Only metallic or asbestos metallic gaskets may be used on flat or raised face flanges if the expected

Page 173

normal service pressure exceeds 720 psi (4960 kPa) or the temperature exceeds 750°F (399°C). However, compressed sheet asbestos confined gaskets are not limited as to pressures, provided the gasket material is suitable for the temperatures.

FIG. NC-3647.2-1 TYPES OF PERMANENT BLANKS

FIG. NC-3647.2-1 TYPES OF PERMANENT BLANKS

(c) The use of metal or metal asbestos gaskets is not limited as to pressure, provided the gasket materials are suitable for the fluid Design Temperature.

NC-3647.6 Bolting

(a) Bolts, stud bolts, nuts, and washers shall comply with applicable standards and specifications listed in Table NC-3132-1. Unless otherwise specified, bolting shall be in accordance with the latest edition of ANSI B16.5. Bolts and stud bolts shall extend completely through the nuts.

(b) Studs shall be threaded full length or shall be machined down to the root diameter of the thread in the unthreaded portion, provided that the threaded portions are at least $1\frac{1}{2}$ diameters in length. Studs greater than 8 diameters in length may have an unthreaded portion which has the nominal diameter of the thread, provided the following requirements are met:

(1) the threaded portions shall be at least $1\frac{1}{2}$ diameters in length;

(2) the stud shall be machined down to the root diameter of the thread for a minimum distance of 0.5 diameters adjacent to the threaded portion; and

(3) a suitable transition shall be provided between the root diameter and unthreaded portions.

(c) Carbon steel bolts shall be ANSI Standard square or heavy hexagon head bolts and shall have ANSI Standard heavy semifinished hexagon nuts.

(d) Alloy steel stud bolts shall have ANSI Standard heavy hexagon nuts. Headed alloy bolts are not recommended.

Page 174

(e) It is recommended that all alloy bolts or stud bolts and accompanying nuts be threaded in accordance with ANSI B1.1 Class 2A external threads and Class 2B internal threads.

NC-3648 Reducers

Reducer fittings manufactured in accordance with the standards listed in Table NC-3132-1 shall be considered suitable for use. Where butt welding reducers are made to a nominal pipe thickness, the reducers shall be considered suitable for use with pipe of the same nominal thickness.

NC-3649 Pressure Design of Other Pressure Retaining Piping Products

Other pressure retaining piping products manufactured in accordance with the standards listed in Table NC-3132-1 shall be considered suitable for use in piping systems at the specified pressure-temperature ratings. Pressure retaining piping products not covered by the standards listed in Table NC-3132-1 and for which design equations or procedures are not given in this Subsection may be used where the design of similarly shaped, proportioned, and sized components has been proved satisfactory by successful performance under comparable service conditions. Where such satisfactory service experience exists, interpolation may be made to other sized piping products with a geometrically similar shape. In the absence of such service experience, the pressure design shall be based on an analysis consistent with the general design philosophy of this Subsection and substantiated by at least one of the following:

(a) proof tests as described in ANSI B16.9;

(b) experimental stress analysis (Appendix II).

NC-3649.1 Expansion Joints - General Requirements.

Expansion joints of the bellows, sliding, ball, or swivel types may be used to provide flexibility for piping systems. The design of the piping systems and the design, material, fabrication, examination, and testing of the expansion joints shall conform to this Subsection and shall comply with the requirements of (a) through (e) below.

(a) Piping system layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the expansion joints other than those for the absorption of which they are both suitable and intended. Bellows

expansion joints are normally not designed for absorbing torsion. Sliding expansion joints are normally not designed for absorbing bending.

In sliding and bellows expansion joints used for absorbing axial motion, the hydrostatic end force caused by fluid pressure and the forces caused by either friction resistance or spring force, or both, should be resisted by rigid end anchors, cross connections of the section ends, or other means. Where reaction to hydrostatic end forces acts on pipe, guides shall be provided to prevent buckling in any direction. For bellows expansion joints, the pipe guiding and anchorage shall conform to EJMA Standards.²⁴

(b) The expansion joints shall be installed in such locations as to be accessible for scheduled inspection and maintenance and for removal and replacement either directly or by other suitable means.

(c) Expansion joints employing mechanical seals shall be sufficiently leak-tight to satisfy safety requirements. The system designer shall specify the leak-tightness criteria for this purpose.

(d) Materials shall conform to the requirements of NC-2000, except that no sheet material in the quenched, aged, or air-hardened condition shall be used for the flexible element of a bellows joint. If heat treatment is required, it shall be performed either after welding the elements into a complete cylinder or after all forming of the bellows is completed, the only welding permissible after such treatment being that required to connect the element to pipe or end flanges.

(e) All welded joints shall comply with the requirements of NC-4800.

NC-3649.2 Bellows Expansion Joints.

Expansion joints of the bellows type may be used to provide flexibility for piping systems. The design, material, fabrication, examination, and testing of the expansion joints shall conform to this Subsection and the requirements of (a) through (f) below.

(a) The piping system layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the bellows other than those for which they have been designed.

24 Expansion Joint Manufacturers Association, 331 Madison Avenue, New York, NY 10017.

(b) In all systems containing bellows, the hydrostatic end force caused by pressure and the bellows spring force shall be accommodated by or resisted by rigid anchors, cross connections of the expansion joint ends, or other means. Where bellows are used in straight pipe sections to absorb axial motion and where the hydrostatic end force of the bellows acts on the pipe as a column, guides must be provided to prevent buckling of the pipe in any direction. The pipe guiding

Page 175

and anchorage shall conform to the requirements of the Design Specifications for the attached piping.

(c) The expansion joints shall be installed in such locations as to be accessible for scheduled inspection, where applicable.

(d) The joints shall be provided with bars or other suitable members for maintaining the proper face-to-face dimension during shipment and installation. Bellows shall not be extended or compressed to make up deficiencies in length of offset to accommodate connected piping which is not properly aligned, unless such misalignments have been specified by the system designer.

(e) The expansion joints shall be marked to show the direction of flow, if applicable, and shall be installed in accordance with this marking.

(f) Unless otherwise stated in the Design Specifications, internal sleeves shall be provided when flow velocities exceed the following values:

Air, steam, and other gases

Up to 6 in. diameter - 4 ft/sec/in. of diameter

Over 6 in. diameter - 25 ft/sec/in. of diameter

Water and other liquids

Up to 6 in. diameter - 2 ft/sec/in. of diameter

Over 6 in. diameter - 10 ft/sec/in. of diameter

NC-3649.3 Bellows Expansion Joint Materials.

Pressure retaining materials in the expansion joint shall conform to the requirements of NC-2000.

[98]

NC-3649.4 Bellows Expansion Joint Design.

Bellows may be of the unreinforced or reinforced convoluted type or of the toroidal type. The design shall conform to the requirements of NC-3000 and to those of (a) through (j) below.

(a) The circumferential membrane stresses in both the bellows and reinforcing member, due to pressure, shall not exceed the allowable stresses given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(b) The sum of the bellows meridional membrane and bending stresses due to internal pressure shall not exceed a value which results in a permanent decrease in the spaces between adjacent convolutions of 7% after a pressure test of $1\frac{1}{2}$ times the Design Pressure, adjusted for temperature.

(c) The ratio of the internal pressure, at which the bellows will become unstable (squirm), to the equivalent cold service pressure shall exceed 2.25. By definition, squirm shall be considered to have occurred if under internal pressure an initially symmetrical bellows deforms, resulting in a lack of parallelism or uneven spacing of adjacent convolutions at any point on the circumference. Unless otherwise specified, this deformation shall be construed as unacceptable squirm when the ratio of the maximum convolution pitch under internal pressure to the convolution pitch before application of pressure exceeds 1.15 for unreinforced and 1.20 for reinforced bellows. In the case of universal expansion joints, which consist of two bellows joined by a cylindrical section, compliance with these criteria shall be satisfied by the entire assembly. No external restraints on the bellows shall be employed during squirm testing other than those which will exist after installation.

(1) For single joints used in axial or lateral motion, the squirm test may be performed with the bellows fixed in the straight position at the maximum length expected in service; for rotation and universal joints, the bellows shall be held at the maximum design rotation angle or offset movement. In the case of single joints subjected to rotation movement or universal joints subjected to lateral offset movement, an instability condition as previously defined may or may not appear. Instead, movement of the convolutions may occur due to the superposition of the lateral internal pressure component on the applied rotation. In such cases, that portion of the bellows deformation due to the design rotation angle or offset movement should not be included in the deformation used to define squirm.

(2) In the case of squirm tests, the equivalent cold service pressure is defined as the Design Pressure multiplied by the ratio E_c/E_R where E_c and E_R are defined as the modulus of elasticity of the bellows material at room temperature and normal service temperature, respectively.

(d) The combination of meridional membrane and bending stresses S in the bellows due to internal pressure and deflection, multiplied by a stress factor K_s ,²⁵ shall not exceed the value defined by the following equation:

$$K_s \times S = S_f$$

where

K_s	$= K_{sc} \times K_{ss}$, but not less than 1.25
K_{sc}	$=$ factor for differences in design fatigue curves at temperatures greater than 100°F
	$= 2S_c / (S_c + S_R)$
K_{ss}	$=$ factor for the statistical variation in test results
	$= 1.470 - 0.044 \times \text{number of replicate tests}$

²⁵ See Appendix II, II-1520(g).

S

= total combined meridional membrane and bending stress due to pressure and deflection, psi. The calculation of the individual stress components and their combination must be determined by the same method as used for determining S_f . In the case of single joints subjected to rotation

Page 176

movement and universal joints subjected to lateral offset movement, the increase in deflection stress caused by the lateral internal pressure component shall be included in determining the combined stress.

S_f

= total combined stress to failure at design cyclic life (number of cycles to failure) obtained from plots of stress versus cyclic life based on data from fatigue tests of a series of bellows at a given temperature (usually room temperature) evaluated by a best fit continuous curve or series of curves, psi. The S_f plot shall be parallel to the best fit curve and shall lie below all of the data points.

S_c

= basic material allowable stress value at room temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi

S_h

= basic material allowable stress value at normal service temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi

(e) Compliance with (a), (b), (c), and (d) above shall be demonstrated by any one of the procedures of (1), (2), or (3) below.

(1) Calculation of the individual stresses, their combination and relation to fatigue life may be performed by any analytical method based on elastic shell theory. The resulting equations must be substantiated by correlation with actual tests of a consistent series of bellows of the same basic design (unreinforced, reinforced, and toroidal bellows are considered as separate designs) by each manufacturer in order to demonstrate predictability of rupture pressure, meridional yielding, squirm, and cyclic life. A minimum of five burst tests on bellows of varying sizes, with not less than three convolutions, shall be conducted to verify that the analytical method will adequately satisfy criteria (a) and (b) above. No specimen shall rupture at less than four times its equivalent cold pressure rating. A minimum of ten squirm tests on bellows of varying diameters and number of convolutions shall be conducted to verify that the analytical method will adequately satisfy (c) above. Since column instability is most likely to occur in bellows less than 20 in. diameter, where the convoluted bellows length is greater than its diameter, the test specimens shall reflect these considerations. In the case of universal expansion joints, two additional tests shall be conducted to verify that the analytical method will adequately satisfy (c) above. The cyclic life versus combined stress plot used in evaluating NC-3649.4(d) shall be obtained from the results of at least 25 fatigue tests on bellows of varying diameters, thicknesses, and convolution profiles. These curves may be used for diameter and convolution profiles other than those tested, provided that a variation in these dimensions has been included in the correlation with test data. Each group of five such tests on varying bellows may be considered the equivalent of one replicate test in determining K_s .

(2) Individual expansion joint designs may be shown to comply by the testing of duplicate bellows. At least two test specimens are required, one to demonstrate pressure capacity in accordance with (a), (b), and (c) above and the second to demonstrate fatigue life in accordance with (d) above. In the case of rupture and fatigue tests, the specimens need not possess a duplicate number of convolutions, provided the number of convolutions is not less than three and the diameter, thickness, depth, and pitch of the specimen are identical to the part to be furnished; squirm test specimens shall possess the total number of convolutions.

(a) Any or all of the above tests of (e)(1) or (e)(2) may be conducted at room temperature, provided that cold service pressure is defined as the Design Pressure multiplied by the ratio of S_c/S_h for rupture specimens and E_c/E_h for

squirm specimens.

(b) The fatigue life of the test specimen shall exceed $K_s^{4.3}$ times the number of design cycles specified for the most significant cyclic movements. This test shall include the effect of internal pressure. If lateral and rotation movements are specified, these may be converted to equivalent axial motion for cyclic testing; the convolution deflection produced by the lateral component of the internal pressure force during the squirm test for single rotation joints and universal joints shall be added to the mechanical deflections in determining fatigue life. Where accelerated fatigue testing is employed, the deflection and number of cycles required shall be in accordance with Appendix II. Cumulative fatigue requirements can be satisfied in accordance with NC-3649.4(g) without additional testing by assuming that the slope of the fatigue curve is 4.3 and that the curve passes through the test point.

(3) An individual design may be shown to comply by a design analysis in accordance with NC-3200. The stresses at every point in the bellows shall be determined by either elastic shell theory or by a plastic analysis, where applicable. Where an elastic analysis is employed, the stress intensity values of Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 and fatigue curves of Tables I-9.0 may be used to evaluate the design.

(a) The stability requirements of NC-3649.4(c) may be demonstrated by either:

(1) elastic stability calculations, provided that the ratio of the internal pressure at which the bellows is predicted to become unstable to the equivalent cold service pressure exceeds 10; or

Page 177

(2) the pressure test of NC-6230, provided that the test is conducted at $2^{1/4}$ times the equivalent cold design pressure, and single rotation and universal joints are held at their design rotation angle or offset movement during the test and the requirements of NC-3649.4(b) are not exceeded by such a test.

(f) The Certificate Holder's Data Report shall state which of the above procedures was utilized to verify the design.

(g) If there are two or more types of stress cycles which produce significant stresses, their cumulative effect shall be evaluated as stipulated in Steps 1 through 5 below.

Step 1: Designate the specified number of times each stress cycle of types 1, 2, ..., n , will be repeated during the life of the component as $n_1, n_2, \dots, n_n$ respectively.

NOTE: In determining $n_1, n_2, \dots, n_n$ consideration shall be given to the superposition of cycles of various origins which produce a total stress difference $S_1, S_2, \dots, S_n$ greater than the stress difference of the individual cycles. For example, if one type of stress cycle produces 1,000 cycles of stress difference variation from zero to +60,000 psi and another type of stress cycle produces 10,000 cycles of a stress difference variation from zero to - 50,000 psi, the two types of cycles to be considered are defined by the following parameters:

Type 1 cycle $n_1 = 1000$,

$$S_1 = (60,000 + 50,000) = 110,000 \text{ psi}$$

Type 2 cycle $n_2 = 9000$,

$$S_2 = (50,000 + 0) = 50,000 \text{ psi}$$

Step 2: For each value $S_1, S_2, \dots, S_n$ use the applicable design fatigue curve and corresponding method of analysis to determine the maximum number of stress cycles which would be allowable if this type of cycle were the only one acting. Call these values $N_1, N_2, \dots, N_n$. The fatigue curve used may be either the S_r plot defined in NC-3649.4(d) or the curve consistent with NC-3649.4(e)(2) or (3). If the fatigue curve has been developed based on a total stress difference, then the full value of $S_1, S_2, \dots, S_n$ of Step 1 must be used to determine N ; however, if the curve is based on an alternating stress, then the values $S_1, S_2, \dots, S_n$ become the alternating stresses.

Step 3: For each type of stress cycle, calculate the usage factors, $U_1, U_2, \dots, U_n$ from $U_1 = n_1/N_1, U_2 = n_2/N_2, \dots, U_n = n_n/N_n$

Step 4: Calculate the cumulative usage factor U from $U = U_1 + U_2 + \dots + U_n$

Step 5: The cumulative usage factor U shall not exceed 1.0.

(h) The Certificate Holder shall submit a report which demonstrates compliance with NC-3649.

(i) Where necessary to carry the pressure, the cylindrical ends of the bellows may be reinforced by suitable collars. The design method used to assure that the stresses generated will not cause premature failure of the bellows material or weldment shall include the attachment weld between the bellows and end connections.

(j) The spring rates of the expansion joint assembly shall be provided by the Certificate Holder. The spring rates of a bellows can be defined by several methods due to the hysteresis loop which can occur during deflection; a restoring force may be required to return the bellows to the original neutral position after deflection. When applicable, the Design Specifications shall state the maximum allowable force that can be imposed on the connecting parts or shall require the Certificate Holder to determine the maximum force necessary to deflect the bellows a given distance, such as the maximum movement to be absorbed.

[98]

NC-3650 ANALYSIS OF PIPING SYSTEMS

NC-3651 General Requirements²⁶

(a) The design of the complete piping system shall be analyzed between anchors for the effects of thermal expansion, weight, and other sustained and occasional loads. The system design shall meet the limits of NC-3650. The pressure portion of Eqs. (8) and (9) may be replaced with the expression

$$S_{LP} = B_1 \frac{2Pd^2}{D_o^2 - d^2}$$

The pressure portion of Eq. (11) may be replaced by the expression

$$S_{LP} = \frac{Pd^2}{D_o^2 - d^2}$$

where the terms are the same as in NC-3652, except

P	= P or $P_{\max}$, psi
d	= nominal inside diameter of pipe, in.

(b) When evaluating stresses in the vicinity of expansion joints, consideration must be given to actual cross-sectional areas that exist at the expansion joint.

(c) For analysis of flanged joints, see NC-3658.

NC-3652 Consideration of Design Conditions

The effects of pressure, weight, and other sustained mechanical loads must meet the requirements of Eq. (8):

26 The pressure term in Eqs. (8), (9), and (11) may not apply for bellows and expansion joints.

Page 178

$$S_{SL} = B_1 \frac{PD_o}{2t_n} + B_2 \frac{M_A}{Z} \leq 1.5S_h \quad (8)$$

(8)

B_1, B_2	= primary stress indices for the specific product under investigation [Fig. NC-3673.2(b)-1]
P	= internal Design Pressure, psi
D_o	= outside diameter of pipe, in.
t_n	= nominal wall thickness, in.
M_A	= resultant moment loading on cross section due to weight and other sustained loads, in.-lb (NC-3653.3)
Z	= section modulus of pipe, in. ³
S_h	= basic material allowable stress at Design Temperature, psi

NC-3653 Consideration of Level A and B Service Limits

NC-3653.1 Occasional Loads.²⁷

The effects of pressure, weight, other sustained loads, and occasional loads, including nonreversing dynamic loads, for which Level B Service Limits are designated, must meet the requirements of Eq. (9):

$$S_{OL} = B_1 \frac{P_{\max} D_o}{2t_n} + B_2 \left(\frac{M_A + M_B}{Z} \right) \leq 1.8 S_h \quad (9)$$

(9)

but not greater than $1.5S_y$. Terms are the same as in NC-3652, except:

$P_{\max}$	= peak pressure, psi
M_B	= resultant moment loading on cross section due to nonreversing dynamic loads.
S_y	= material yield strength at temperature consistent with the loading under consideration, psi
S_h	= material allowable stress at temperature consistent with the loading under consideration, psi

NC-3653.2 Thermal Expansion.

For Service Loadings for which Level A and B Service Limits are designated, the requirements of either Eq. (10), or Eq. (11), and Eq. (11a) must be met.

(a) The effects of thermal expansion must meet the requirements of Eq. (10):

$$S_E = \frac{iM_C}{Z} \leq S_A \quad (10)$$

(10)

Terms same as above except:

27 Design Pressure may be used if the Design Specification states that peak pressure and earthquake need not be taken as acting concurrently.

M_C	= range of resultant moments due to thermal expansion, in.-lb.; also include moment effects of anchor displacements due to nonreversing dynamic loads if anchor displacement effects were omitted from Eq. (9) (NC-3653.1)
S_A	= allowable stress range for expansion stresses (NC-3611.2), psi

i

= stress intensification factor (NC-3673.2)

(b) The effects of any single nonrepeated anchor movement shall meet the requirements of Eq. (10a):

$$\frac{iM_D}{Z} \leq 3.0S_c \quad (10a)$$

(10a)

Terms same as in NC-3653.2, except:

M_D

= resultant moment due to any single nonrepeated anchor movement (e.g., predicted building settlement), in.-lb.

(c) The effects of pressure, weight, other sustained loads, and thermal expansion shall meet the requirements of Eq. (11):

$$S_{TE} = \frac{PD_o}{4t_n} + 0.75i\left(\frac{M_A}{Z}\right) + i\left(\frac{M_C}{Z}\right) \leq (S_h + S_A) \quad (11)$$

(11)

0.75*i* shall not be less than 1.0.

(d) The effects of reversing dynamic loads must meet the requirements of Eq. (11a):

$$S_R = \frac{iM_R}{Z} \leq 2.0S_A \quad (11a)$$

(11a)

Terms same as in NC-3653.2, except:

M_R

= range of resultant moments due to inertia and anchor motion effects of reversing dynamic loads

NC-3653.3 Determination of Moments and Section Modulus

(a) For purposes of Eqs. (8), (9), (10), and (11), the resultant moment for straight through components, curved pipe, or welding elbows may be calculated as follows. Determine resultant moment:

$$M_j = [M_{xj}^2 + M_{yj}^2 + M_{zj}^2]^{1/2}$$

where

j

= A, B, C, or D which are the subscripts of M_A, M_B, M_C, M_D defined in NC-3652, NC-3653.1, and NC-3653.2

(b) When evaluating Eqs. (8) and (9) for branch connections and tees, use the procedure for branch and

Page 179

run moments given in NB-3683.1(d). When evaluating Eqs. (10), (10a), and (11), use (c) and (d) below.

**FIG. NC-3653.3-1 REDUCING OR FULL OUTLET
BRANCH CONNECTIONS OR TEES**

FIG. NC-3653.3-1 REDUCING OR FULL OUTLET BRANCH CONNECTIONS OR TEES

(c) For full outlet branch connections, calculate the resultant moment of each leg separately in accordance with (a) above. Moments are to be taken at the junction point of the legs (Fig. NC-3653.3-1).

(d) For reduced outlets, calculate the resultant moment of each leg separately in accordance with (a) above. Moments are to be taken at the junction point of the legs (Fig. NC-3653.3-1), except that for $r'_m/r < 0.5$ the branch moments at the outside surface of the run pipe may be used for the branch leg. For the reduced outlet branch:

$$M_A M_B M_C M_D = \sqrt{M_{x3}^2 + M_{y3}^2 + M_{z3}^2}$$

and

$$Z = \pi (r'_m)^2 t_s, \text{ in.}^3, \text{ except as otherwise defined in Fig. NC-3673.2(b)-1}$$

r = run pipe mean cross-sectional radius, in.

r'_m = branch mean cross-sectional radius, in.

t_s = effective branch wall thickness, in.

= lesser of T_r or iT_b

T_b = nominal branch wall thickness, in.

T_r = nominal wall thickness of run pipe, in.

For the main run outlets, use $M_A M_B$ and M_C as defined in NC-3653.3(a).

NC-3654 Consideration of Level C Service Limits

NC-3654.1 Permissible Pressure.

When Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are specified, the permissible pressure shall not exceed the pressure P_a calculated in accordance with Eq. (5) of NC-3641.1, by more than 50%.

[98]

NC-3654.2 Analysis of Piping Components.

For Service Loadings for which Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are designated, the requirements of (a) or (b) below shall apply.

(a) For Service Loadings for which Level C Service Limits are designated, which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the conditions of Eq. (9) of NC-3653.1 shall be met using Service Level C coincident pressure P and moments M_{ii} which result in the maximum calculated stress. The allowable stress to be used for this condition is $2.25S_h$ but not greater than $1.8S_y$.

(b) For Service Loadings for which Level C Service Limits are designated, which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of NC-3655(b) shall be satisfied, using the allowable stress in NC-3656(b)(2), 70% of the allowable stress in NC-3655(b)(3), and 70% of the allowable loads in NC-3656(b)(4).

[98]

NC-3654.3 Deformation Limits.

Any deformation or deflection limits prescribed by the Design Specifications shall be considered with respect to Level C Service Limits.

[98]

NC-3655 Consideration of Level D Service Limits

If the Design Specifications specify any Service Loading for which Level D Limits are designated [NCA-2142.2(b)(4)], the requirements of (a), (b), or (c) below shall apply.

(a) For Service Loadings for which Level D Service Limits are designated, which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the requirements of (1) and (2) below shall apply.

(1) The permissible pressure shall not exceed 2.0 times the pressure P_a calculated in accordance with Eq. (3) of NC-3641.1.

(2) The conditions of Eq. (9) of NC-3653.1 shall be met. The allowable stress to be used for this condition is $3.0 S_{Hr}$ but not greater than $2.0 S_y$.

Page 180

(b) For piping fabricated from material designated P-No. 1 through P-No. 9 in Table 2A, Section II, Part D, and limited to $D_o/t_n \leq 50$, if Level D Service Limits are designated, which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of (1) through (5) below shall apply.

(1) The pressure occurring coincident with the earthquake or other reversing type loading shall not exceed the Design Pressure.

(2) The sustained stress due to weight loading shall not exceed the following:

$$B_2 \frac{D_o}{2I} M_W \leq 0.5 S_m$$

where

M_W

= resultant moment due to weight effects

(3) The stress due to weight and inertial loading due to reversing dynamic loads in combination with the Level D coincident pressure shall not exceed the following:

$$B_1 \frac{P_D D_O}{2t} + B_2 \frac{D_O}{2I} M_E \leq 4.5 S_m$$

where

P_D

= the pressure occurring coincident with the reversing dynamic load

M_E

= the amplitude of the resultant moment due to the inertial loading from the earthquake, other reversing type dynamic events and weight. Earthquake and other reversing dynamic loads shall be computed from a linear elastic response spectrum analysis as defined in Appendix N-1226, except the spectrum peak broadening value Δ_{fg} in N-1226.3 shall not be less than 15% and, in place of the damping values for both large and small diameter piping systems in Table N-1230-1 for Operating Basis Earthquake and Safe Shutdown Earthquake, a value of 5 shall be used. The ground motion design input for generating the floor response spectrum to be used in the linear elastic analysis shall meet the requirements of Appendix N-1211(a) and N-1211(b). Moments and forces may be computed using a methodology other than prescribed above if the alternate methodology is demonstrated to produce results which envelope the prescribed methodology results. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment. If the method of analysis is such that only magnitude without algebraic signs are obtained, the most conservative combination shall be assumed.

(4) The range of the resultant moment M_{am} and the amplitude of the longitudinal force F_{am} resulting from the anchor motions due to earthquake and other reversing type dynamic loading shall not exceed the following:

$$C_2 \frac{M_{AM} D_O}{2I} < S_1$$

$$\frac{F_{AM}}{A_M} < S_2$$

where

$$S_1 = 6S_m$$

$$S_2 = 1.0S_m$$

$$A_M = \text{cross-sectional area of metal in the piping component wall}$$

(5) Piping displacements shall satisfy Design Specification limitations.

(c) As an alternative to NC-3655(a) and (b), the rules contained in Appendix F may be used in evaluating these service loadings independently of all other Design and Service Loadings.

[98]

NC-3658 Analysis of Flanged Joints

The pressure design of flanged joints is covered by NC-3647.1. Flanged joints subjected to combinations of moment and pressure shall meet the requirements of either NC-3658.1, NC-3658.2, or NC-3658.3. In addition, the pipe-to-flange welds shall meet the requirements of NC-3651 through NC-3655 using appropriate stress intensification factors from Fig. NC-3673.2(b)-1. The following nomenclature applies for NC-3658:

P	= Design or Service Condition Pressure as defined in NCA-2140, psi
P_{eq}	= equivalent pressure to account for the moments applied to the flange joint during the Condition, psi
M_{fs}	= bending or torsional moment (considered separately) applied to the joint due to weight, thermal expansion of the piping, sustained anchor movements, relief valve steady-state thrust, and other sustained mechanical loads applied to the flanged joint during the design or service condition, in.-lb. If cold springing is used, the moment

Page 181

	may be reduced to the extent permitted by NC-3673.5.
M_{fd}	= bending or torsional moment (considered separately) as defined for M_{fs} but including dynamic loadings applied to the flanged joint during the design or service condition, in.-lb
G	= diameter at location of gasket load reaction as defined in XI-3130, in.
A_b	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, sq in.
C	= bolt circle diameter, in.
S	= allowable bolt stress for the bolt material, psi
S_y	= yield strength, psi, of flange material at Design Temperature (Section II, Part D, Tables Y-1 and Y-2)
D_f	= outside diameter of raised face, in.
P_{fd}	= pressure concurrent with M_{fd} , psi

NC-3658.1 Any Flanged Joint.

Flanged joints may be analyzed and the stresses evaluated by using the methods given in Appendix XI as modified by NC-3658.1(a) or by NC-3658.1(b). Alternatively, they may be analyzed in accordance with Appendix XIII.

(a) If the flanged joint conforms to one of the standards listed in Table NC-3132-1, and if each P' as calculated by NC-3658.1(b) is less than the rated pressure at the Design or Service Temperature utilized, the requirements of NC-3658 are satisfied.

(b) The Design Pressure used for the calculation of H in Appendix XI shall be replaced by a flange design pressure

$$P' = P + P_{eq}$$

The equivalent pressure P_{eq} shall be determined by the greater of:

$$P_{eq} = 16M_{fs}/\pi G^3$$

or

$$P_{eq} = 8M_{fd}/\pi G^3$$

NC-3658.2 Standard Flanged Joints at Moderate Pressures and Temperatures.

Flanged joints conforming to ANSI B16.5, MSS SP-44, API 605, or AWWA C207 Class E [275 psi (1900 kPa)], and used where neither the Design nor Service Pressure exceeds 100 psi (690 kPa) and neither the Design nor Service Temperature exceeds 200°F (93°C), meet the requirements of NC-3658, provided the following equations are satisfied:

$$M_{fs} \leq A_b CS/4$$

and

$$M_{fd} \leq A_b CS/2$$

NC-3658.3 ANSI B16.5 Flanged Joints With High Strength Bolting.

Flanged joints using flanges, bolting, and gaskets as specified in ANSI B16.5 and using bolting material having an S value at 100°F (38°C) not less than 20,000 psi (138 MPa) may be analyzed in accordance with the following rules.

(a) Design Limits and Levels A and B Service Limits

(1) The pressure shall not exceed the rated pressure for Level A Service Limits or 1.1 times the rated pressure for Level B Service Limits.

(2) The limitations given by Eqs. (12) and (13) shall be met:

$$(12) M_{fs} \leq 3125(S_y/36,000)CA_b$$

$$(13) M_{fd} \leq 6250(S_y/36,000)CA_b$$

where the value of $S_y/36,000$ shall not be taken as greater than unity.

(b) Level C Service Limits

(1) The pressure shall not exceed 1.5 times the rated pressure.

(2) The limitation given by Eq. (17) shall be met:

$$(17) M_{fd} \leq [11,250A_b - (\pi/16) D_f^2 P_{fd}] C (S_y/36,000)$$

where the value of $S_y/36,000$ shall not be taken as greater than unity.

(c) Level D Service Limits

(1) The pressure shall not exceed 2.0 times the rated pressure.

(2) The limitation given by Eq. (17) shall be met, where P_{fd} and M_{fd} are pressures, psi, and moments, in.-lb, occurring concurrently.

(d) *Test Loadings.* Analysis for test loadings is not required.

Page 182

NC-3660 DESIGN OF WELDS

NC-3661 Welded Joints

NC-3661.1 General Requirements.

Welded joints shall be made in accordance with NC-4200.

NC-3661.2 Socket Welds²⁸

(a) Socket welded piping joints shall be limited to pipe sizes of 2 in. (DN 50) and less.

(b) Socket welds shall comply with the requirements of NC-4427.

(c) Drains and bypasses may be attached to a valve or a fitting using socket weld joints.

NC-3661.3 Fillet Welds and Partial Penetration Welds for Branch Connections²⁹

(a) Fillet welds and partial penetration welds may be used within the limitations of NC-3643.1(c).

(b)

- (b) For fillet welds, the size of the weld shall be specified on the design drawings.
- (c) For partial penetration welds, the size of the weld, the depth of the weld groove, and the groove angle shall be specified on the design drawings.

NC-3670 SPECIAL PIPING REQUIREMENTS

NC-3671 Selection and Limitations of Nonwelded Piping Joints

The type of piping joint used shall be suitable for the Design Loadings and shall be selected with consideration of joint tightness, mechanical strength, and the nature of the fluid handled.

NC-3671.1 Flanged Joints.

Flanged joints shall conform to NC-3647 and NC-3658.

NC-3671.2 Expanded or Rolled Joints.

Expanded or rolled joints may be used when experience or test (NC-3649) has demonstrated that the joint is suitable for the Design Loadings and when adequate provisions are made to prevent separation of the joint.

NC-3671.3 Threaded Joints.

Threaded joints may be used within the limitations specified in (a), (b), and (c) below.

28 Socket welds should not be used where the existence of crevices could accelerate corrosion.

29 Fillet and partial penetration welds should not be used where severe vibration is expected.

(a) All threads on piping products shall be taper pipe threads in accordance with the applicable standard listed in Table NC-3132-1. Threads other than taper pipe threads may be used for piping components where tightness of the joint depends on a seal weld or a seating surface other than the threads and when experience or test (NC-3649) has demonstrated that such threads are suitable.

(b) Threaded joints shall not be used when severe erosion, crevice corrosion, shock, or vibration is expected to occur. Size limits for steam and hot water service above 220°F (104°C) shall be as follows:

Maximum Nominal Size, in.	Maximum Pressure, psi
3	400
2	600
1	1200
3/4 and less	1500

(c) Pipe with a wall thickness less than that of standard weight of ANSI B36.10 steel pipe shall not be threaded, regardless of service. When steel pipe is threaded and used in steam service above 250 psi (1720 kPa) or water service above 100 psi (690 kPa) and 220°F (104°C), the pipe shall be seamless and at least Schedule 80.

NC-3671.4 Flared, Flareless, and Compression Joints.

Flared, flareless, and compression type tubing fittings may be used for tube sizes not exceeding 2 in. (51 mm) O.D. within the limitations of applicable standards and specifications in Table NC-3132-1 and as specified in (a) through (e) below.

(a) Fittings and their joints shall be compatible with the tubing with which they are to be used and shall conform to the range of wall thicknesses and method of assembly recommended by the manufacturer.

(b) Fittings shall be used at pressure-temperature ratings not exceeding the recommendations of the manufacturer. Service conditions, such as vibration and thermal cycling, shall be considered in the application.

(c) All threads on piping products shall be taper pipe threads in accordance with applicable standard listed in Table NC-3132-1. Exceptions are that threads other than taper pipe threads may be used for piping components where tightness of the joint depends on a seating surface other than the threads and when experience or tests (NC-3649) have demonstrated that such threads are suitable.

(d) In the absence of standards or specifications, the designer shall determine that the type of fitting selected is adequate and safe for the Design Loadings in accordance with the following requirements.

(1) The pressure design shall meet the requirements of NC-3649.

(2) Prototypes of the fittings to be used shall successfully meet performance tests (NC-3649) to determine the safety of the joint under simulated Service Loadings. When vibration, fatigue, cyclic conditions,

Page 183

low temperature, thermal expansion, or hydraulic shock are expected, the applicable conditions shall be incorporated in the test.

(e) Flareless fittings shall be of a design in which the gripping member or sleeve shall grip or bite into the outer surface of the tube with sufficient strength to hold the tube against pressure but without appreciably distorting the inside tube diameter. The gripping member shall also form a pressure seal against the fitting body.

(1) When using bite-type fittings, a spot check shall be made for adequate depth of bite and condition of tubing by disassembling and reassembling selected joints.

(2) Grip-type fittings that are tightened in accordance with manufacturer's instructions need not be disassembled for checking.

NC-3671.5 Caulked Joints.

Caulked or leaded joints shall not be used.

NC-3671.6 Brazed and Soldered Joints

(a) *Brazed Joints.* Brazed joints shall be socket type, and minimum socket depth shall be sufficient for the intended service (Fig. NC-4511-1).

(b) *Soldered Joints.* Soldered joints shall be socket type and shall be made in accordance with applicable standards listed in Table NC-3132-1.

(c) *Limitations of Brazed and Soldered Joints*

(1) Brazed socket-type joints shall not be used in systems containing flammable or toxic fluids or in areas where fire hazards are involved.

(2) Soldered socket-type joints shall be limited to systems containing nonflammable and nontoxic fluids.

(3) Soldered socket-type joints shall not be used in piping subject to mechanical or thermal shock or vibration.

(4) Brazed or soldered joints depending solely upon a fillet, rather than primarily upon brazing or soldering material between the pipe and socket, are not acceptable.

(5) Soldered joints shall be pressure and temperature rated in accordance with the applicable standards in Table NC-3132-1, except that they shall not be used at pressures in excess of 175 psi (1207 kPa) or at temperatures in excess of 250°F (121°C).

NC-3671.7 Sleeve Coupled and Other Patented Joints.

Coupling-type, mechanical gland-type, and other patented joints may be used where experience or tests have demonstrated to the satisfaction of the designer that the joint is safe for the Design Loadings and when adequate provision is made to prevent separation of the joint.

NC-3672 Expansion and Flexibility

NC-3672.1 General Requirements

(a) In addition to the design requirements for pressure, weight, and other loadings, piping systems subject to thermal expansion or contraction or to similar movements imposed by other sources shall be designed in accordance with the requirements for the evaluation and analysis of flexibility and stresses specified in this paragraph.

(b) Piping shall meet the expansion and flexibility requirements of this Subarticle except that, where Class 2 piping is connected to Class 1 piping, the requirements for expansion and flexibility for Class 1 piping shall apply to the Class 2 piping out to the first anchor on the Class 2 piping. However, the effect of expansion stresses in combination with stresses from other causes shall be evaluated in accordance with NC-3650. Other exceptions as given in the following subparagraphs shall apply.

NC-3672.2 Properties.

Thermal expansion data and moduli of elasticity shall be determined from Tables TE and TM, Section II, Part D, Subpart 2, which cover more commonly used piping materials. For materials not included in these Tables, reference shall be to authoritative source data such as publications of the National Institute of Standards and Technology.

NC-3672.3 Thermal Expansion Range.

The thermal expansion range shall be determined from Table TE, Section II, Part D, Subpart 2 as the difference between the unit expansion shown for the highest metal temperature and that for the lowest metal temperature resulting from service and shutdown conditions.

NC-3672.4 Moduli of Elasticity.

The cold and hot moduli of elasticity E_c and E_h shall be as shown in Table TM, Section II, Part D, Subpart 2 based on the temperatures established in NC-3672.3.

NC-3672.5 Poisson's Ratio.

Poisson's ratio, when required for flexibility calculations, shall be taken as 0.3 at all temperatures for all materials.

NC-3672.6 Stresses.

Calculations for the stresses shall be based on the least cross-sectional area of the pipe or fitting, using nominal dimensions at the location of local strain. Calculations for the expansion stress S_E shall be based on the modulus of elasticity at room temperature E_c .

(a) *Stress Range.* Stresses caused by thermal expansion, when of sufficient initial magnitude, relax in the hot condition as a result of local yielding or creep. A stress reduction takes place and usually appears as a stress of reversed sign when the component returns to

Page 184

the cold condition. This phenomenon is designated as self-springing of the line and is similar in effect to cold springing. The extent of self-springing depends on the material, the magnitude of the initial expansion and fabrication stress, the hot service temperature, and the elapsed time. When the expansion stress in the hot condition tends to diminish with time, the sum of the expansion strains for the hot and cold conditions during any one cycle remains substantially constant. This sum is referred to as the strain range; however, to permit convenient association with allowable stress, stress range is selected as the criterion for the thermal design of piping.

(b) *Local Overstrain.* All the commonly used methods of piping flexibility analysis assume elastic behavior of the entire piping system. This assumption is sufficiently accurate for systems in which plastic straining occurs at many points or over relatively wide regions but fails to reflect the actual strain distribution in unbalanced systems in which only a small portion of the piping undergoes plastic strain or in which, for piping operating in the creep range, the strain distribution is very uneven. In these cases, the weaker or higher stressed portions will be subjected to strain

concentrations due to elastic follow-up of the stiffer or lower stressed portions. Unbalance can be produced:

(1) by use of small pipe runs in series with larger or stiffer pipe, with the small lines relatively highly stressed;

(2) by local reduction in size or cross section, or local use of a weaker material;

(3) in a system of uniform size, by use of a line configuration for which the neutral axis or thrust line is situated close to the major portion of the line itself, with only a very small offset portion of the line absorbing most of the expansion strain.

(c) Conditions of this type shall be avoided where materials of relatively low ductility are used; if unavoidable, they shall be mitigated by the judicious application of cold spring.

(d) It is recommended that the design of piping systems of austenitic materials be approached with greater overall care as to general elimination of local stress raisers, examination, material selection, fabrication quality, and erection.

NC-3672.7 Flexibility.

Piping systems shall be designed to have sufficient flexibility to prevent pipe movements from causing failure from overstress of the pipe material or anchors, leakage at joints, or detrimental distortion of connected equipment resulting from excessive thrusts and moments. Flexibility shall be provided by changes of direction in the piping through the use of bends, loops, or offsets; or provisions shall be made to absorb thermal movements by utilizing expansion, swivel, or ball joints, or corrugated pipe.

NC-3672.8 Expansion, Swivel, or Ball Joints.

Expansion, swivel, or ball joints, if used, shall conform to the requirements and limitations of NC-3649.

NC-3673 Analysis

NC-3673.1 Method of Analysis.

All systems shall be analyzed for adequate flexibility by a structural analysis unless one of the following conditions is met:

(a) the system can be judged technically adequate by an engineering comparison with previously analyzed systems;

(b) the operating temperature of the piping system is at or below 150°F and the piping is laid out with inherent flexibility, as provided in NC-3672.7;

(c) the operating temperature of the piping system is at or below 250°F and the piping is analyzed for flexibility using simplified methods of calculation such as handbooks or charts.

[98]

NC-3673.2 Basic Assumptions and Requirements

(a) When calculating the flexibility of a piping system between anchor points, the system between anchor points shall be treated as a whole. The significance of all parts of the line and of all restraints, such as supports or guides, including intermediate restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, shall be considered.

(b) Comprehensive calculations shall take into account the flexibility factors found to exist in piping products or joints other than straight pipe. Credit may be taken where extra flexibility exists in such products or joints. Flexibility factors and stress intensification factors for commonly used piping products and joints are shown in Fig. NC-3673.2(b)-1. The stress intensification factors and flexibility factors in Fig. NC-3673.2(b)-1 shall be used unless specific experimental or analytical data exist that would warrant lower stress intensification factors or higher flexibility factors.

(c) Flexibility factors are identified herein by k with appropriate subscripts. The general definition of a flexibility factor is:

$$k = \theta_{ab} / \theta_{nom}$$

where

θ_{ab}

= rotation of end a , with respect to end b , due to

Page 185

a moment load M and in the direction of the moment M

θ_{nom}

= nominal rotation of equivalent straight pipe due to moment load M

The flexibility factor k is defined in detail for specific components in Fig. NC-3673.2(b)-1.

(d) Stress intensification factors are identified herein by i . The definition of a stress intensification factor is based on fatigue bend testing of mild carbon steel fittings and is:

$$iS = 245,000 N^{0.2}$$

where

S

= amplitude of the applied bending stress at the point of failure, psi

N

= number of cycles to failure

i

= stress intensification factor

= ratio of the bending moment producing fatigue in a given number of cycles in a straight pipe with a girth butt weld to that producing failure in the same number of cycles in the fitting or joint under consideration.

(e) For piping products or joints not listed in Fig. NC-3673.2(b)-1, flexibility or stress intensification factors shall be established by experimental or analytical means.

(f) Experimental determination of flexibility factors shall be in accordance with Appendix II, II-1900. Experimental determination of stress intensification factors shall be in accordance with Appendix II, II-2000.

(g) Analytical determination of flexibility factors shall be consistent with the definition above.

(h) Analytical determination of stress intensification factors may be based on the empirical relationship

$$i = C_2 K_2 / 2, \text{ but not less than } 1.0$$

where C_2 and K_2 are stress indices for Class 1 piping products or joints from NB-3681(a)-1, or are determined as explained below.

Analytical determination of stress intensification factors shall be correlated with experimental fatigue results. Experimental correlation may be with new test data or with test data from similar products or joints reported in literature. Finite element analyses or other stress analysis methods may be used to determine C_2 ; however, tests or established stress concentration factor data should then be used to determine K_2 .

(i) For certain piping products or joints the stress intensification factor may vary depending on the direction of the applied moment, such as in an elbow or branch connection. For these cases, the stress intensification factor used in Eqs. (10), (10a), and (11) of NC-3653.2 shall be the maximum stress intensification factor for all loading directions as determined in accordance with (f) or (h) above.

(j) Stress intensification factors determined in accordance with (f) above shall be documented in accordance with Appendix II, II-2050. The test report may be included and certified with the Design Report (NCA-3551.1 and NCA-3555) for the individual piping system or a separate report furnished (II-2050).

(k) Stress intensification factors determined in accordance with (h) above shall be documented in a report with sufficient detail to permit independent review. The review shall be performed by an engineer competent in the

applicable field of design in accordance with Appendix XXIII. The report shall be included and certified as part of the design report for the piping system (NCA-3551.1 and NCA-3555).

(l) The total expansion range as determined from NC-3672.3 shall be used in all calculations, whether or not the piping is cold sprung. Expansion of the line, linear and angular movements of the equipment, supports, restraints, and anchors shall be considered in the determination of the total expansion range.

(m) Where simplifying assumptions are used in calculations or model tests, the likelihood of underestimates of forces, moments, and stresses, including the effects of stress intensification, shall be evaluated.

(n) Dimensional properties of pipe and fittings used in flexibility calculations shall be based on nominal dimensions.

(o) When determining stress intensification factors by experimental methods, ND-3653.3(d) shall not apply. The nominal stress at the point under consideration (crack site, point of maximum stress, etc.) shall be used.

[98]

NC-3673.3 Cold Springing.

The beneficial effect of judicious cold springing in assisting a system to attain its most favorable position is recognized. Inasmuch as the life of a system under cyclic conditions depends on the stress range rather than the stress level at any one time, no credit for cold spring is allowed with regard to stresses. In calculating end thrusts and moments acting on equipment, the actual reactions at any one time, rather than their range, shall be used. Credit for cold springing is allowed in the calculations of thrusts and moments, provided the method of obtaining the designed cold spring is specified and used.

Page 186

NC-3673.4 Movements.

Movement caused by thermal expansion and loadings shall be determined for consideration of obstructions and design of proper supports.

[98]

NC-3673.5 Computing Hot and Cold Reactions

(a) In a piping system with no cold spring or an equal percentage of cold springing in all directions, the reactions of R_h and R_c in the hot and cold conditions, respectively, shall be obtained from the reaction R derived from the flexibility calculations based on the modulus of elasticity at room temperature E_c using Eqs. (14) and (15).

$$R_h = \left(1 - \frac{2}{3}C\right) \left[\frac{E_h}{E_c}\right] R \quad (14)$$

$$R_c = CR$$

$$= \left[1 - \frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)}\right] R \quad (15)$$

(14 - 15)

whichever is greater, and with further condition that

$$\frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)} < 1$$

where

C	= cold spring factor varying from zero for no cold spring to 1.00 for 100% cold spring
S_E	= computed expansion stress, psi [NC-3653.2(a)]
E_c	= modulus of elasticity in the cold condition, psi
E_h	= modulus of elasticity in the hot condition, psi

R	= maximum reaction for full expansion range based on E_c which assumes the most severe condition (100% cold spring, whether such is used or not), lb
R_c, R_h	= maximum reactions estimated to occur in the cold and hot conditions, respectively, lb

(b) If a piping system is designed with different percentages of cold spring in various directions, Eqs. (14) and (15) are not applicable. In this case, the piping system shall be analyzed by a comprehensive method. The calculated hot reactions shall be based on theoretical cold springs in all directions not greater than two-thirds of the cold springs as specified or measured.

[98]

NC-3673.6 Reaction Limits.

The reactions computed shall not exceed limits which the attached equipment can safely sustain.

NC-3674 Design of Pipe Supporting Elements

Supporting elements, including hangers, anchors, and sliding supports, shall be designed in accordance with the requirements of Subsection NF.

NC-3677 Pressure Relief Piping

NC-3677.1 General Requirements.

Pressure relief piping within the scope of this Subarticle shall be supported to sustain reaction forces and shall conform to the requirements of the following subparagraphs.

NC-3677.2 Piping to Pressure Relieving Safety Devices

(a) Piping that connects a pressure relief device to a piping system shall comply with all the requirements of the Class of piping of the system which it is designed to relieve.

(b) There shall be no intervening stop valves between systems being protected and their protective device or devices, except as provided for in NC-7142.

NC-3677.3 Discharge Piping From Pressure Relieving Safety Devices

(a) Discharge piping of pressure relief devices shall comply with the requirements of the Class of piping applicable to the conditions under which it operates.

(b) There shall be no intervening stop valves between the protective device or devices and the point of discharge, except as provided for in NC-7142.

(c) When discharging directly to the atmosphere, discharge shall not impinge on other piping or equipment and shall be directed away from platforms and other areas used by personnel.

(d) It is recommended that individual discharge lines be used, but if two or more reliefs are combined:

(1) the discharge piping shall be designed with sufficient flow area so as not to affect operation of the relief devices; and

(2) in no case shall the area of such common lines be less than the combined area of all lines discharging into it.

(e) Discharge lines from pressure relieving safety devices within the scope of this Subarticle shall be designed to facilitate drainage.

(f) When the umbrella or drip pan type of connection is used, the discharge piping shall be so designed as to prevent binding due to expansion movements. Drainage shall be provided to remove water collected above the safety valve seat.

[Notes (1), (2), (11)] (CONT'D)

NOTES TO FIG. NC-3673.2(b)-1:

- (1) Where flanges are attached to one or both ends, the values of k and f shall be corrected by the factor c given below.
 - (a) One end flanged, $c = h/6$
 - (b) Both ends flanged, $c = h/3$
- (2) B_1 and B_2 primary stress indices for these products are in course of preparation. In the interim, use $B_1 = 0.5$ and $B_2 = 0.75$.
- (3) Also includes single miter joints.
- (4) When $t_o > 1.5 t_n$, $h = 4.05 t_o/r$
- (5) The equation applies only if the following conditions are met.
 - (a) The reinforcement area requirements of NC-3643 are met.
 - (b) The axis of the branch pipe is normal to the surface of run pipe wall.
 - (c) For branch connections in a pipe, the arc distance measured between the centers of adjacent branches along the surface of the run pipe is not less than three times the sum of their inside radii in the longitudinal direction or not less than two times the sum of their inside radii along the circumference of the run pipe.
 - (d) The inside corner radius r_1 [Fig. NC-3673.2(b)-2] for nominal branch pipe size greater than 4 in. shall be between 10% and 50% T_r . The radius r_1 is not required for nominal branch pipe size smaller than 4 in.
 - (e) The outer radius r_2 is not less than the larger of $T_p/2$, $(T_b + Y)/2$ [Fig. NC-3673-2 sketch (c)] or $T_p/2$.
 - (f) The outer radius r_3 is not less than the larger of
 - (1) $0.002 \theta d_o$
 - (2) $2 (\sin \theta)^3$ times the offset for the configurations shown in Fig. NC-3673.2(b)-2 sketches (a) and (b).
 - (g) $R_m/T_r \leq 50$ and $r_m/R_m \leq 0.5$.
 - (h) The outer radius r_2 is not required provided an additional multiplier of 2.0 is included in the equations for branch end and run end stress intensification factors. In this case, the calculated value of f for the branch or run shall not be less than 2.1.
- (6) For checking branch leg stress: $Z = \pi(r_m)^2 T_b$.
For checking run leg stress: $Z = \pi(r_m)^2 T_r$.
- (7) In Fig. NC-4427-1(c-1) and (c-2), C_s shall be taken as X_{min} and $C_s \geq 1.25 t_n$. In Fig. NC-4427-1(c-3), $C_s \geq 0.75 t_n$. For unequal leg lengths use the smaller leg length for C_s .
- (8) The equation applies only if the following conditions are met.
 - (a) Cone angle α does not exceed 60 deg.
 - (b) The larger of D_1/t_1 and D_2/t_2 does not exceed 100.
 - (c) The wall thickness is not less than t_1 throughout the body of the reducer, except in and immediately adjacent to the cylindrical portion on the small end, where the thickness shall not be less than t_2 .
 - (d) For eccentric reducers, α is the maximum cone angle.
- (9) Factors shown apply to bending; flexibility factor for torsion equals 0.9.
- (10) The designer is cautioned that cast butt welding elbows may have considerably heavier walls than that of the pipe with which they are used. Large errors may be introduced unless the effect of these greater thicknesses is considered.
- (11) The following nomenclature applies:

r = mean radius of pipe, in. (matching pipe for tees and elbows)
 t_1 = nominal wall thickness of pipe, in. (matching pipe for tees and elbows, see Note (10))
 R = nominal bend radius of elbow or pipe bend, in.
 θ = one-half angle between adjacent miter axes, deg.
 s = miter spacing at center line, in.
 t_o = reinforced thickness, in.
 D_o = nominal outside diameter, in.
- (12) For branch connections nomenclature, refer to Figs. NC-3643.2(b)-2 and NC-3673.2(b)-2.
- (13) The flexibility factors k and stress intensification factors f and stress indices B_2 apply to bending in any plane for fittings and shall in no case be taken less than 1.0. They apply over the effective arc length (shown by heavy center lines in the sketches) for curved and miter elbows, and to the intersection point for tees.
- (14) Primary stress indices are applicable to $D_o/t_n \leq 50$ and stress intensification factors are applicable to $D_o/t_n \leq 100$.

[98]

FIG. NC-3673.2(b)-2 BRANCH DIMENSIONS

NC-3678 Temporary Piping Systems

Prior to service of piping systems and associated equipment, certain temporary piping may be installed to accommodate cleaning by blowing out with steam or air, by acid or caustic fluid circulation, or other flushing methods. Such temporary piping shall be designed to safeguard against rupture or other failure which could become a hazard to health or safety.

NC-3690 DIMENSIONAL REQUIREMENTS FOR PIPING PRODUCTS

NC-3691 Standard Piping Products

Dimensions of standard piping products shall comply with the standards and specifications listed in Table NC-3132-1.

NC-3692 Nonstandard Piping Products

The dimensions of nonstandard piping products shall be such as to provide strength and performance equivalent to standard products, except as permitted in NC-3641.

NC-3700 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

NC-3720 DESIGN RULES

(a) The design of the pressure retaining portion of electrical and mechanical penetration assemblies shall be the same as for vessels (NC-3300).

(b) For closing seams in electrical and mechanical penetration assemblies meeting the requirements of NC-4730(c), the closure head shall meet the requirements of NC-3325 using a factor $C = 0.20$. The fillet weld shall be designed using an allowable stress of 0.5S.

NC-3800 DESIGN OF ATMOSPHERIC STORAGE TANKS

NC-3810 GENERAL REQUIREMENTS

NC-3811 Acceptability

The requirements for acceptability of atmospheric storage tanks are given in the following subparagraphs.

NC-3811.1 Scope.

The design rules for atmospheric storage tanks cover vertical cylindrical flat bottom above ground³⁰ welded tanks at atmospheric pressure. These tanks may contain liquids such as refueling water, condensate, borated reactor coolant, or liquid radioactive waste. Such tanks may be within building structures, depending upon the liquid to be contained, or they may be above grade exposed to atmospheric conditions.

NC-3811.2 Design Requirements.

The design rules for atmospheric storage tanks shall conform to the design requirements of NC-3100 and NC-3300 except as they may be modified by the requirements of this Subarticle. The specific design requirements shall be stipulated in the Design Specifications.

NC-3812 Design Report

The Certificate Holder manufacturing a storage tank conforming to the design requirements of this Subarticle is required to provide a Design Report as part of his responsibility for achieving structural integrity of the tank. The Design Report shall be certified when required by NCA-3550.

NC-3820 DESIGN CONSIDERATIONS

NC-3821 Design and Service Loadings

(a) Loadings shall be identified as Design or Service, and if Service, they shall have Level A, B, C, or D Service Limits designated (NCA-2142).

(b) The provisions of NC-3110 shall apply.

(c) The stress limits given in NC-3821.5 shall be met.

NC-3821.1 Design Pressure.

The Design Pressure³¹ shall be atmospheric.

NC-3821.2 Design Temperature.

The Design Temperature shall not be greater than 200°F (93°C).

NC-3821.3 Loadings.

The requirements of NC-3111 shall be met.

NC-3821.4 Welded Joint Restrictions.

The restrictions given in (a) through (c) below on type and size of joints or welds shall apply.

(a) Tack welds shall not be considered as having any strength value in the finished structure.

30 These rules do not limit storage tanks from being installed below grade or below ground provided the tanks are not subject to external pressure resulting from earth or fill.

31 The limitation of the Design Pressure to atmospheric is not intended to preclude the use of these tanks at vapor pressure slightly above or below atmospheric within the range normally required to operate vent valves. If these pressures or vacuums exceed $\frac{1}{2}$ oz/sq in., especially in combination with large diameter tanks, the forces involved may require special consideration in the design.

**TABLE NC-3821.5-1
DESIGN AND SERVICE LIMITS**

Service Limits	Stress Limits [Notes (1), (2)]
Design and Level A	$\sigma_m \leq 1.0 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5 S$
Level B	$\sigma_m \leq 1.10 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65 S$
Level C	$\sigma_m \leq 1.5 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8 S$
Level D	$\sigma_m \leq 2.0 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4 S$

NOTES:

(a) See NC-3921.5 for definitions of symbols.

(b) These limits do not take into account either local or general buckling which might occur in thin-wall vessels.

TABLE NC-3821.5-1 DESIGN AND SERVICE LIMITS

(b) The minimum size of fillet welds shall be in accordance with NC-4246.6.

(c) All nozzle welds shall be in accordance with NC-4246.5.

NC-3821.5 Limits of Calculated Stresses for Design and Service Loadings.

Stress³² limits for Design and Service Loadings are specified in Table NC-3821.5-1. The symbols used in Table NC-3821.5-1 are defined as follows:

σ_m

= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.

σ_L

= local membrane stress, psi. This stress is the same as σ_m except that it includes the effect of discontinuities.

σ_b

= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.

S

= allowable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

32 Stress means the maximum normal stress.

Typical examples of locations and loadings for which σ_m , σ_L , and σ_b are applicable are shown in Table XIII-1130-1, with σ considered as equivalent to P in Table XIII-1130-1.

NC-3830 BOTTOM DESIGN

NC-3831 Plate Sizes

(a) All bottom plates shall have a minimum nominal thickness of $1/4$ in. exclusive of any corrosion allowance required by the Design Specifications.

(b) Bottom plates shall be ordered of sufficient size so that, when trimmed, at least a 1 in. (25 mm) width will project beyond the outside edge of the weld attaching the bottom to the shell plate.

(c) The type of foundation used for supporting the tank shall be taken into account in the design of the bottom plates and welds. For recommended practice for construction of foundations see API-650, Appendix B.

NC-3832 Methods of Construction

Bottoms shall be built to either one of the alternative methods of construction given in NC-4246.1.

NC-3833 Shell-to-Bottom Attachment

The requirements for shell-to-bottom attachments are given in NC-4246.2.

NC-3840 SHELL DESIGN

NC-3841 Loads

(a) Thicknesses shall be computed on the basis of the specific gravity of the stored material but in no case shall the specific gravity be less than 1.00. The tension in each ring shall be computed 12 in. (305 mm) above the center line of the lower horizontal joint of the course in question. In computing these stresses, the tank diameter shall be taken as the nominal diameter of the bottom course.

(b) Isolated radial loads on tank shells, such as caused by heavy loads on platforms and elevated walkways between tanks, shall be distributed by rolled structural sections, plate ribs, or built-up members, preferably in a horizontal position.

Page 194

NC-3842 Diameters and Thicknesses of Shell Plates

(a) For method of determining minimum thicknesses³³ of shell plates, see NC-3324.3. For pressure retaining material, see NC-2121.

(b) In no case shall the nominal thickness³⁴ of shell plates be less than the following:

**Nominal Tank
Diameter,³⁵ ft**

**Nominal
Thickness, in.**

50 to 120, incl.

$$\frac{3}{16} \\ \frac{1}{4}$$

(c) The maximum nominal thickness of tank shell plates shall be $1\frac{1}{2}$ in. (38 mm).

NC-3843 Arrangement of Members

(a) The tank shell shall be designed to have all courses vertical. Unless otherwise specified, abutting shell plates at horizontal joints shall have a common vertical center line of thickness. Vertical joints in adjacent shell courses shall not be in alignment but shall be offset from each other a minimum distance of 6 in. (152 mm).

(b) Except as specified for self-supporting roofs and for tanks having the flanged roof-to-shell detail described in (c) below, tank shells shall be supplied with top angles of not less than the following sizes: tanks 35 ft (10.6 m) and smaller in diameter - $2\frac{1}{2}$ in. $\times$ $2\frac{1}{2}$ in. $\times$ $\frac{1}{4}$ in. (64 mm $\times$ 64 mm $\times$ 6 mm); tanks of more than 35 ft to 60 ft (10.6 m to 18.3 m), inclusive, in diameter - $2\frac{1}{2}$ in. $\times$ $2\frac{1}{2}$ in. $\times$ $\frac{5}{16}$ in. (64 mm $\times$ 64 mm $\times$ 8 mm); tanks larger than 60 ft (18.3 m) in diameter - 3 in. $\times$ 3 in. $\times$ $\frac{3}{8}$ in. (76 mm $\times$ 76 mm $\times$ 10 mm). The outstanding leg of the top angle may extend inside or outside the tank shell.

(c)(1) For tanks not exceeding 35 ft (10.6 m) in diameter and having supported cone roofs, the top edge of the shell may be flanged in lieu of installing a top angle. The radius of bend and the width of the flanged edge shall conform to the details of Fig. NC-4246.3-1 sketch (c).

33 Any specified corrosion allowance for the shell plates shall be added to the calculated thickness.

34 The nominal thickness of shell plates refers to the tank shell as constructed. The thicknesses specified are based on erection requirements.

35 Nominal tank diameter shall be the center line diameter of the shell plates unless otherwise stipulated in the Design Specifications.

(2) This construction may be used for any tank having a self-supporting roof if the total cross-sectional area of the junction fulfills the stated area requirements for the top angle construction. No additional member, such as an angle or bar, shall be added to the flanged roof-to-shell detail.

(d) For tanks not exceeding 35 ft (10.6 m) in diameter and having a supported flat roof, the roof plates may be flanged and butt welded to the shell. The flanged tank roof plates shall be butt welded. The inside radius of the knuckle shall not be less than $1.75t$ nor more than $8t$.

NC-3850 ROOF DESIGN

NC-3851 Types of Roofs

The types of roofs are defined in the following subparagraphs.

NC-3851.1 Supported Cone Roof.

A supported cone roof is a roof formed to approximately the surface of a right cone, with its principal support provided by either rafters on girders and columns or rafters on trusses with or without columns.

NC-3851.2 Supported Flat Roof.

A supported flat roof is a roof which is essentially flat, with its principal support provided by either rafters supported by the shell without columns or by rafters in conjunction with girders and trusses with or without columns.

NC-3851.3 Self-Supporting Cone Roof.

A self-supporting cone roof is a roof formed to approximately the surface of a right cone, supported only at its periphery.

NC-3851.4 Self-Supporting Dome Roof.

A self-supporting dome roof is a roof formed to approximately a spherical surface, supported only at its periphery.

A self-supporting dome roof is a roof formed to approximately a spherical surface, supported only at its periphery.

NC-3851.5 Self-Supporting Umbrella Roof.

A self-supporting umbrella roof is a modified dome roof so formed that any horizontal section is a regular polygon with as many sides as there are roof plates, supported only at its periphery.

NC-3852 General Roof Design Requirements

NC-3852.1 Loading Requirements.

All roofs and supporting structures shall be designed to support dead load, plus a uniform live load of not less than 25 lb/sq ft of projected area unless otherwise specified, except that tanks installed in an enclosed area, not exposed to the elements, shall be designed to support the dead load plus a uniform live load of not less than 10 lb/sq ft.

NC-3852.2 Minimum Plate Thickness.

Roof plates shall have a minimum nominal thickness of $\frac{3}{16}$ in.

Page 195

(4.8 mm). A greater thickness may be required for self-supporting roofs. Any specified corrosion allowance for the plates of self-supporting roofs shall be added to the calculated thickness. Any specified corrosion allowance for plates of supported roofs shall be added to the minimum nominal thickness.

NC-3852.3 Minimum Thickness of Supporting Members.

All internal and external structural members shall have a minimum nominal thickness, in any component, of 0.17 in.

NC-3852.4 Attachment of Roof Plates.

Roof plates shall be attached to the top angle of the tank in accordance with NC-4246.3. Roof plates of supported roofs shall not be attached to internal supporting members.

NC-3852.5 Welding of Roof Plates

(a) If the continuous fillet weld between the roof plates and the top angle does not exceed $\frac{3}{16}$ in. (4.8 mm) and the slope of the roof at the top angle attachment does not exceed 2 in./ft (16.7%), the joint may be considered to serve as an emergency venting device which, in case of excessive internal pressure, will fail before failure occurs in the tank shell joints or the shell-to-bottom joint. Failure of the roof-to-shell joint may be accompanied by buckling of the top angle.

(b) Where the weld size exceeds $\frac{3}{16}$ in. (4.8 mm) or where the slope of the roof at the top angle attachment is greater than 2 in./ft (16.7%), emergency venting devices conforming to the specifications noted in API Standard 2000³⁶ shall be provided. The Certificate Holder shall provide a suitable tank connection for the device.

(c) Roof plates shall be welded in accordance with NC-4246.4.

NC-3852.6 Allowable Stresses.³⁷

All parts of the structure shall be so proportioned that the sum of the static stresses shall not exceed the values given in (a) through (d) below.

(a) Tension

(1) in rolled steel, on net section, 20 ksi (138 MPa);

(2) in full penetration groove welds on the thinner plate area, 18 ksi (124 MPa).

(b) Compression

36 API Standard 2000, 1968 Edition, Venting Atmospheric and Low Pressure Storage Tanks, American Petroleum Institute, 1801 K Street, N.W., Washington, D.C., 20036.

37 The decrease in yield stress at Design Temperature shall be taken into account.

- (1) in rolled steel, where lateral deflection is prevented, 20.0 ksi (138 MPa);
- (2) in full penetration groove welds on the thinner plate area, 20.0 ksi (138 MPa);
- (3) in columns, on cross-sectional area, ksi; for L/r not over 120,

$$\left[1 - \frac{(L/r)^2}{34,700} \right] \frac{33Y}{FS}$$

for L/r over 120 to 131.7, inclusive:

$$\frac{\left[1 - \frac{(L/r)^2}{34,700} \right] \frac{33Y}{FS}}{1.6 - L/200r}$$

for L/r over 131.7:

$$\frac{149,000Y}{(L/r)^2 (1.6 - L/200r)}$$

where

L

= unbraced length of column, in

r

= least radius of gyration of column, in.

FS

= design factor

=

$$= \frac{5}{3} + \left[\frac{(L/r)}{350} \right] - \left[\frac{(L/r)^3}{18,300,000} \right]$$

Y

= 1.0, for structural sections or tubular sections having t/R values equal to or exceeding 0.015

= $[(200/3)(t/R)] [2 - (200/3)(t/R)]$, for tubular sections having t/R values less than 0.015

t

= thickness of tubular section, in.; $\frac{1}{4}$ in. minimum for main compression members, $\frac{3}{16}$ in. minimum for bracing and other secondary members

R

= outside radius of tubular section, in.

For main compression members, the ratio L/r shall not exceed 180. For bracing and other secondary members, the ratio L/r shall not exceed 200.

(c) Bending

(1) In tension and compression on extreme fibers of rolled shapes and built-up members with an axis of symmetry in

the plane of loading where the laterally unsupported length of compression flange is no greater than 13 times its width, the compression flange width-thickness ratio does not exceed 17, and the web depth-thickness ratio does not exceed 22.0 ksi (152 MPa).

(2) In tension and compression on extreme fibers of unsymmetrical members where the member is supported laterally at intervals no greater than 13 times its compression flange width, 20.0 ksi (138 MPa).

Page 196

(3) In tension on extreme fibers of other rolled shapes, built-up members, and plate girders, 20 ksi (138 MPa).

(4) In compression on extreme fibers of other rolled shapes, plate girders, and built-up members having an axis of symmetry in the plane of loading, the larger value, ksi, computed by the following:

$$20 - \frac{0.571}{1000} \left(\frac{l}{r} \right)^2$$

or

$$\frac{12,000}{(ld / A_f)} \leq 20$$

where

l

= unbraced length of compression flange, in.

r	= radius of gyration of section about an axis in the plane of loading, in.
d	= depth of section, in.
A_f	= area of compression flange, sq in.

Compression, ksi, on extreme fibers of other unsymmetrical sections:

$$\frac{12,000}{(ld / A_f)} \leq 20$$

(d) Shearing

(1) In fillet, plug, slot and partial penetration groove welds across throat area, 13.6 ksi.

(2) On the gross area of the webs of beams and girders when t is the thickness of the web, inches and h , the clear distance between web flanges, inches, is not more than $60t$, or when the web is adequately stiffened, 13.0 ksi.

(3) On the gross area of the webs of beams and girders, if the web is not stiffened so that h is more than $60t$, the greatest average shear V/A , ksi, shall not exceed:

$$\frac{19.5}{1 + h^2 / 7200t^2}$$

where V is the total shear, kips, and A is the gross area of the web, sq in.

NC-3853 Supported Cone Roofs - General Requirements

NC-3853.1 Slope of Roof.

The slope of the roof shall be $\frac{3}{4}$ in./ft (6.25%) or greater. If the rafters are set directly on chord girders, producing slightly varying rafter slopes, the slope of the flattest rafter shall conform to the specified roof slope.

NC-3853.2 Main Supporting Members.

Main supporting members, including those supporting the rafters, may be rolled or fabricated sections or trusses. Although these members may be in contact with the roof plates, the compression flange of a member or the top chord of a truss shall be considered to receive no lateral support from the roof plates and shall be laterally braced, if necessary, by other acceptable methods. The allowable stresses in these members shall be governed by NC-3852.6.

NC-3853.3 Design of Rafters.

Structural members, serving as rafters, may be rolled or fabricated sections but in all cases shall conform with the rules of NC-3852 through NC-3853. Rafters in direct contact with the roof plates applying the loading to the rafters may be considered to receive adequate lateral support from the friction between the roof plates and the compression flanges of the rafters, with the following exceptions:

- (a) trusses and open web joints used as rafters;
- (b) rafters having a nominal depth greater than 15 in. (381 mm);
- (c) rafters having a slope greater than 2 in./ft (16.7%).

NC-3853.4 Spacing of Rafters.

Rafters shall be spaced so that, in the outer ring, their centers shall not be more than 6.28 ft (1.9 m) apart, measured along the circumference of the tank. Spacing on inner rings shall not be greater than $5\frac{1}{2}$ ft (1.7 m).

NC-3853.5 Roof Columns.

Roof columns shall be made from structural shapes or pipe.

NC-3853.6 Attachment of Rafter Clips and Column Base Clip Guides.

Rafter clips for the outer row of rafters shall be welded to the tank shell. Column base clip guides shall be welded to the tank bottom to prevent lateral movement of column bases. All other structural attachments shall be either bolted or welded.

NC-3853.7 Welding of Roof Plates.

Roof plates shall be welded in accordance with NC-4246.4. The size of the roof to top angle weld shall be $\frac{3}{16}$ in. (4.8 mm) or less.

NC-3854 Supported Flat Roofs

NC-3854.1 General Requirements.

The use of supported flat roofs shall be limited to tanks having diameters not greater than 35 ft (10.6 m). The design of

Page 197

supported flat roofs shall be in accordance with NC-3853 except as noted below.

NC-3854.2 Main Supporting Members

- (a) Requirements of NC-3853.1 do not apply.
- (b) Supporting structural members may be either internal or external to the roof plate.
- (c) External rafters shall not be welded to the top angle or attached to the shell plate.
- (d) External rafters shall be welded to the roof plate. The weld shall be sized to carry the combined dead and live loads on the roof plate.

NC-3855 Self-Supporting Cone Roofs

NC-3855.1 Nomenclature.

The symbols used are defined as follows:

A_t	= combined cross-sectional area of roof plate, shell plate and top shell angle, sq in.
D	= nominal diameter of tank shell, ft
θ	= angle of cone elements with the horizontal, deg.
f	= tensile working stress for the material of the roof plates, shell plates, or top shell angle, whichever is the least value, at the service temperature, psi
P	= dead load of roof, plus the live load, lb/sq ft
R	= radius of curvature of roof, ft
t_r	= nominal thickness of roof plates, in.

NC-3855.2 Design Requirements.

Self-supporting cone roofs shall conform to the requirements³⁸ of (a) through (c) below.

- (a) *Slope*

Maximum $\theta = 37$ deg. (tangent = 9:12)

Minimum $\sin \theta = 0.165$ [slope 2 in./ft (16.7%)]

(b) Plate Thickness

(1) Minimum $t_r = D/400 \sin \theta$ but not less than $\frac{3}{16}$ in.

Maximum $t_r = \frac{1}{2}$ in.

(2) Self-supporting roofs having the roof plates stiffened by sections welded to the plates need not conform to the minimum thickness requirements but shall be not less than $\frac{3}{16}$ in.

38 The equations applying to self-supporting roofs provided for a uniform live load of 25 lb/sq ft.

(c) Top Angle to Roof-to-Shell Joint. The cross-sectional area of the top angle, sq in., plus the cross-sectional areas of the shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top angle, shall equal or exceed:

$$\frac{D^2}{3000 \sin \theta}$$

NC-3856 Self-Supporting Dome and Umbrella Roofs

NC-3856.1 Nomenclature.

See NC-3855.1 for nomenclature.

NC-3856.2 Design Requirements.

Self-supporting dome and umbrella roofs shall conform to the requirements³⁴ of (a) through (c) below.

(a) Radius of Curvature

$R = D$ unless otherwise specified

Minimum $R = 0.80D$

Maximum $R = 1.2 D$

(b) *Plate Thickness*

(1) Minimum $t = R/200$ but not less than $\frac{3}{16}$ in.

Maximum $t = \frac{1}{2}$ in.

(2) Self-supporting roofs having the roof plates stiffened by sections welded to the plates need not conform to the minimum thickness requirements but shall be not less than $\frac{3}{16}$ in.

(c) *Top Angle to Roof-to-Shell Joint.* The cross-sectional area of the top angle, sq in., plus the cross-sectional areas of the shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top angle, shall equal or exceed:

$$\frac{DR}{1500}$$

NC-3856.3 Top Angle Attachment for Self-Supporting Roofs

(a) The top angle sections for self-supporting roofs shall meet the requirements of NC-4246.4.

(b) For self-supporting roofs, the edges of the roof plates may be flanged horizontally to rest flat against the top angle to improve welding conditions.

Page 198

Table NC-3861-1
ROOF MANHOLES
See Fig. NC-3861-1; All Dimensions Are in Inches

24	24	30	27½	20	25½	30	24⅝	46

Table NC-3861-1 ROOF MANHOLES

NC-3860 TANK CONNECTIONS AND APPURTENANCES

NC-3861 Roof Manholes

Roof manholes shall conform to Fig. NC-3861-1 and Table NC-3861-1, except that alternative designs which provide equivalent strength are permissible if agreed to by the Owner or his designee.

NC-3862 Roof Nozzles

(a) Flanged roof nozzles shall conform to Fig. NC-3862(a)-1 and Table NC-3862(a)-1. Threaded nozzles shall conform to Fig. NC-3862(a)-2 and Table NC-3862(a)-2. Alternative designs for flanged roof nozzles and threaded nozzles can be used, provided they are of equivalent strength and agreed to by the Owner or his designee.

(b) Roof nozzles are not intended to take loads from pipe reactions. Earthquake loadings need not be considered.

NC-3863 Bottom Outlet Elbows

Bottom outlet elbows shall conform to Fig. NC-3863-1 and Table NC-3863-1.

NC-3864 Threaded Connections

Threaded piping connections shall be female and shall be tapered. The threads shall conform to the requirements for taper pipe threads included in ANSI B1.20.1.

NC-3865 Platforms, Walkways, and Stairways

Platforms, walkways, and stairways shall be in accordance with Tables NC-3865-1 through NC-3865-3.

NC-3866 Nozzle Piping Transitions

The stress limits of Table NC-3821.5-1 shall apply to all portions of nozzles which lie within the limits of reinforcement given in NC-3334, except as provided in NC-3867. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of NC-3600.

NC-3867 Consideration of Standard Reinforcement

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of NC-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table NC-3821.5-1. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are to be designed for, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table NC-3821.5-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case, the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit specified for σ_m in Table NC-3821.5-1 for a given loading.

NC-3900 0-15 psi STORAGE TANK DESIGN

NC-3910 GENERAL REQUIREMENTS

NC-3911 Acceptability

NC-3911.1 Scope.

The design rules for 0-15 psi (0-103 kPa) storage tanks shall cover above ground²⁹ welded storage tanks. These tanks may contain liquids

or gases such as refueling water, condensate, borated reactor coolant, or radioactive waste. Such tanks are normally located within building structures.

FIG. NC-3861-1 ROOF MANHOLES

TABLE NC-3862(a)-1 FLANGED ROOF NOZZLES

FIG. NC-3862(a)-1 FLANGED ROOF NOZZLES

TABLE NC-3862(a)-2 SCREWED OR SOCKET WELD ROOF NOZZLES

FIG. NC-3862(a)-2 SCREWED OR SOCKET WELD ROOF NOZZLES
See Table NC-3862(a)-2, NC-3864

FIG. NC-3862(a)-2 SCREWED OR SOCKET WELD ROOF NOZZLES

NC-3911.2 Design Requirements

(a) The design requirements for 0-15 psig (0-103 kPa) storage tanks shall conform to the design rules of NC-3100 and NC-3300, except where they may be modified by the requirements of this Subarticle. The specific design requirements shall be stipulated in the Design Specifications.

(b) The total liquid capacity of a tank shall be defined as the total volumetric liquid capacity below the high liquid design level. The nominal liquid capacity of a tank shall be defined as the total volumetric liquid capacity between the plane of the high liquid design level and the elevation of the tank grade immediately adjacent to the wall of the tank or such other low liquid design level as the Certificate Holder shall stipulate.

NC-3912 Design Report

The Certificate Holder of a storage tank conforming to the design requirements of this Subarticle is required to provide a Design Report as part of his responsibility

Page 202

for achieving structural integrity of the tank. The Design Report shall be certified when required by NCA-3550.

8	13	12¾	9¾	16½	18

NOTE:

(1) Extra-strong pipe, refer to ANSI B36.10.

TABLE NC-3863-1 WELDED BOTTOM OUTLET ELBOW

GENERAL NOTES:

- (a) Slip-on welding and welding neck flanges shall conform to the requirements for 150 lb forged carbon steel raised face flanges as given in ANSI B16.5.
- (b) Plate ring flanges shall conform to all dimensional requirements for slip-on welding flanges, except that the extended hub on the back of the flange may be omitted.

FIG. NC-3863-1 TYPICAL WELDED BOTTOM OUTLET ELBOW
See Table NC-3863-1

FIG. NC-3863-1 TYPICAL WELDED BOTTOM OUTLET ELBOW

TABLE NC-3865-1 PLATFORMS AND WALKWAYS

-
1. All parts to be made of metal.
 2. Width of floor level (min.): 24 in.
 3. Flooring to be made of grating or nonslip material.
 4. Height of top railing above floor [Note (1)]: 42 in.
 5. Height of toeboard (min.): 3 in.
 6. Space between top of floor and bottom of toeboard (max.): $\frac{1}{4}$ in.
 7. Height of midrail: approximately one-half the distance from top of walkway to top of railing.
 8. Distance between railing posts (max.): 96 in.
 9. The completed structure shall be capable of supporting a moving concentrated load of 1000 lb, and the handrailing structure shall be capable of withstanding a load of 200 lb applied in any direction at any point on the top rail.
 10. Handrails to be on both sides of platform, discontinuing where necessary for access.
 11. At handrail openings, any space between tank and platform wider than 6 in. should be floored.
 12. Tank runways, which extend from one part of a tank to any part of an adjacent tank or to ground or other structure, shall be so supported as to permit free relative movement of the structures joined by the runway. This may be accomplished by firm attachment of runway to one tank, but with a slip joint at point of contact between runway and other tank. This is to permit either tank to settle or be disrupted by an explosion without endangering the other.
-

NOTE:

- (1) Handrail height as required by ANSI specifications. This height is mandatory in some states.

TABLE NC-3865-1 PLATFORMS AND WALKWAYS

NC-3920 DESIGN CONSIDERATIONS

NC-3921 Design and Service Loadings

(a) Conditions shall be identified as Design or Service, and if Service, they shall have Service Limits designated Level A, Level B, or Level C, or Level D (NCA-2142).

(b) The provisions of NC-3110 shall apply.

(c) The stress limits of NC-3921.6 shall be met.

³⁹ Whenever a tank is to be operated with liquid levels which at no time reach the top of the roof but is to be filled to the top of the roof during the hydrostatic test, it shall be designed for both of these maximum liquid level conditions, using in each case the density of the liquid employed. If a tank is not designed to be filled to the top of the roof, overfill protection is required.

NC-3921.1 Design Pressure

(a) The walls of the gas or vapor space and other components of the tank above the maximum liquid level³⁹ at the top of the tank shall be designed for a pressure not less than that at which the pressure relief valves are to be set⁴⁰ and for the maximum partial vacuum which can be developed in such space⁴¹ when the inflow of air, gas, or vapor through the vacuum relief valves is at its maximum specified rate. The maximum positive gage pressure for which this space is designed shall be understood to be the nominal pressure rating for the tank and shall not exceed 15 psi (103 kPa).

**TABLE NC-3865-2
STAIRWAYS**

-
1. All parts to be made of metal.
 2. Width of stairs (min.): 24 in.
 3. Angle [Note (1)] of stairway with a horizontal line (max.): 50 deg.
 4. Width of stair treads (min.): 8 in. [The run defined as the horizontal distance between the noses of successive tread pieces) and the rise of stair treads shall be such that the sum of twice the rise, plus the run, shall be not less than 24 in. nor more than 26 in. Rises shall be uniform throughout the height of the stairway.]
 5. Treads to be made of grating or nonslip material.
 6. Top railing shall join platform handrail without offset, and the height measured vertically from tread level at nose of tread shall be 30 to 34 in.
 7. Distance between railing posts (max.) measured along slope of railing: 96 in.
 8. The completed structure shall be capable of supporting a moving concentrated load of 1000 lb, and the handrailing structure shall be capable of withstanding a load of 200 lb applied in any direction at any point on the top rail.
 9. Handrails shall be on both sides of straight stairs; also, handrails shall be on both sides of circular stairs when the clearance between tank shell and stair stringer exceeds 8 in.
 10. Circumferential stairways should be completely supported on the shell of the tank, and ends of the stringers should be clear of the ground.
-

NOTE:

- (1) It is recommended that the same angle be employed for all stairways in a tank group or plant area.
-

TABLE NC-3865-2 STAIRWAYS

(b) All portions of the tank at levels below maximum liquid level shall be designed for the most severe combination of gas pressure or partial vacuum and static liquid head.

40 A suitable margin shall be allowed between the pressure normally existing in the gas or vapor space and the pressure at which the relief valves are set so as to allow for the increases in pressure caused by variations in the temperature or gravity of the liquid contents of the tank and other factors affecting the pressure in the gas or vapor space.

41 This partial vacuum shall be greater than that at which the vacuum relief valves are set to open.

TABLE NC-3865-3 STAIRWAY RISE, RUN, AND ANGLE RELATIONSHIPS

NC-3921.2 Design Temperature.

The Design Temperature shall not be greater than 200°F (93°C).

NC-3921.3 Tank Shape.

Tank walls shall be so shaped as to avoid any pockets on the inside where gases may become trapped when the liquid level is being raised or pockets on the outside where rainwater may collect.

NC-3921.4 Loadings.

The requirements of NC-3111 shall be met.

NC-3921.5 Corrosion Allowance.

When corrosion is expected on any part of the tank wall or on any external or internal supporting or bracing members upon which the safety of the completed tank depends, additional metal thickness in excess of that required by the design computations shall be provided or some satisfactory method of protecting these surfaces from corrosion shall be employed. Such added thickness need not be the same for all zones of exposure inside and outside the tank.

NC-3921.6 Linings.

When corrosion resistant linings are attached to any element of the tank wall, including nozzles, their thickness shall not be included in the computation for the required wall thickness.

NC-3921.7 Welded Joint Restrictions.

The restrictions on type and size of joints or welds given in (a) through (c) below apply.

(a) Tack welds shall not be considered as having any strength value in the finished structure.

(b) The minimum size of fillet welds shall be in accordance with NC-4247.6.

(c) All nozzle welds shall be in accordance with NC-4244.

NC-3921.8 Limits of Calculated Stresses for Design and Service Loadings.

Stress⁴² limits for Design and Service Loadings are specified in Table NC-3921.6-1. The symbols used in Table NC-3921.6-1 are defined as follows:

σ_m	= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, psi. This stress is the same as σ_m except that it excludes the effect of discontinuities.
σ_b	= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations and is produced only by pressure and other mechanical loads.
S	= allowable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

⁴² Stress means the maximum normal stress.

**TABLE ND-3921.6-1
DESIGN AND SERVICE LIMITS
FOR STEEL TANKS**

Service Limit	Stress Limits [Note (1), (2)]
Design and Level A	$\sigma_m \leq 1.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$
Level B	$\sigma_m \leq 1.10S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$

NOTES:

(1) See NC-3921.6 for definitions of symbols.

(2) These limits do not take into account either local or general buckling which might occur in thin-wall vessels.

TABLE ND-3921.6-1 DESIGN AND SERVICE LIMITS FOR STEEL TANKS

Typical examples of locations and loadings for which σ_m , σ_L , and σ_b are applicable are shown in Table XIII-1130-1, with σ in Table NC-3921.6-1 considered as equivalent to P in Table XIII-1130-1.

NC-3922 Maximum Allowable Stress Values for Tanks

NC-3922.1 Nomenclature.

The symbols used are defined as follows:

t = thickness, in., of sidewalls, roof, or bottom, including

	corrosion allowance.
c	= allowance for corrosion, in.
R	= radius of the tank wall, in.
R_1	= radius of curvature of the tank wall in a meridian plane, in.
R_2	= length, in., of the normal to the tank wall measured from the wall of the tank to its axis of revolution
T_1	= meridional unit force in the wall of the tank, lb/in. of latitudinal arc
T_2	= latitudinal unit force in the wall of the tank, lb/in. of meridional arc
S_{ts}	= maximum allowable stress for simple tension, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)
S_{cs}	= maximum allowable longitudinal compressive stress, psi, for a cylindrical wall acted upon by an axial load with neither a tensile nor a compressive force acting concurrently in a circumferential direction and determined in accordance with NC-3922.3(a) for the thickness-radius ratio involved
S_{ta}	= allowable tensile stress, psi, which is lower than S_{ts} because of the presence of a coexistent compressive stress perpendicular to it
S_{ca}	= allowable compressive stress, psi, which is lower than S_{cs} because of the presence of a coexistent tensile or compressive stress perpendicular to it
S_{tc}	= computed tensile stress, psi, at the point under consideration
S_{cc}	= computed compressive stress, psi, at the point under consideration
S_t	= general symbol for indicating a tensile stress, psi, which may be either an allowable or computed value depending on the context in which the symbol is used
S_c	= general symbol for indicating a compressive stress, psi, which may be either an allowable or computed value, depending on the context in which the symbol is used
N	= ratio of the tensile stress S_t to the maximum allowable stress for simple tension S_{ts}
M	= ratio of the compressive stress S_c to the maximum allowable compressive stress S_{cs} (Fig. NC-3922.1-2)

NC-3922.2 Maximum Tensile Stresses.

The maximum tensile stresses in the outside walls of a tank, as determined for any loadings or any concurrent combination of such loadings shall not exceed the applicable stress values determined in accordance with (a) or (b) below.

(a) If both the meridional and latitudinal unit forces T_1 and T_2 are tensile, or if one of these forces is tensile and the other is zero, the computed tensile stress S_{tc} shall not exceed the applicable value given in Tables 1A, 1B, and 3, Section

Page 206

(b) If the meridional unit force T_1 is tensile and the coexistent latitudinal unit force T_2 is compressive, or if T_2 is tensile and T_1 is compressive, the computed tensile stress S_{tc} shall not exceed a value of S_{ta} obtained by multiplying the applicable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 by the appropriate value of N obtained from Fig. NC-3922.1-1 for the value of compressive stress ($S_c = S_{cc}$) and co-related ratio of $(t - c)/R$ involved. However, in cases where the unit force acting in compression does not exceed 5% of the coexistent tensile unit force

acting perpendicular to it, the designer may permit a tensile stress of the magnitude specified in (a) above. Section F.1 of Appendix F of API 620 Feb. 1970 Ed.⁴³ gives examples illustrating the determination of allowable tensile stress values S_{ta} . In no event shall the value of S_{ta} exceed the allowable stress for simple tension shown in Tables 1A, 1B, and 3, of Section II, Part D, Subpart 1.

**FIG. NC-3922.1-1 BIAXIAL STRESS CHART FOR COMBINED TENSION AND COMPRESSION,
30,000 psi TO 38,000 psi YIELD STRENGTH STEELS**

FIG. NC-3922.1-1 BIAXIAL STRESS CHART FOR COMBINED TENSION AND COMPRESSION, 30,000 psi TO 38,000 psi YIELD STRENGTH STEELS

NC-3922.3 Maximum Compressive Stresses.

Except as provided in NC-3933.4(b), the maximum compressive stresses in the outside walls of a tank, as determined for the loadings, shall not exceed the applicable stress values determined in accordance with (a) through (d) below.

43 Recommended Rules for Design and Construction of Large, Welded, Low-Pressure Storage Tanks, published by American Petroleum Institute, 1801 K St., N.W., Washington, D.C. 20036.

(a) If a cylindrical wall, or portion thereof, is acted upon by a longitudinal compressive force with neither a tensile nor a compressive force acting concurrently in a circumferential direction, the computed compressive stress S_{cc} shall not

exceed a value S_{cs} established for the applicable thickness-radius ratio as follows:⁴⁴

for $(t - c)/R$ values less than 0.00667:

$$S_{cs} = 1,800,000 \frac{t - c}{R}$$

for $(t - c)/R$ values between 0.00667 and 0.0175:

$$S_{cs} = 10,150 + 277,400 \frac{t - c}{R}$$

for $(t - c)/R$ values greater than 0.0175:

⁴⁴ These rules do not apply when the circumferential stress on a cylindrical wall is compressive as in a cylinder acted upon by external pressure.

$$N^2 + MN + M^2 = 1$$

or

$$(S_t/S_{ts})^2 + (S_t/S_{ts})(S_c/S_{cs}) + (S_c/S_{cs})^2 = 1$$

where

$$N = S_t/S_{ts}$$

S_t = the tensile stress, at the point under consideration

S_{ts} = the maximum allowable stress for simple tension

$$M = S_c/S_{cs}$$

S_c = the compressive stress, at the point under consideration

S_{cs} = the maximum allowable longitudinal compressive stress, for a cylindrical wall acted upon by an axial load with neither a tensile nor a compressive force acting concurrently in a circumferential direction; determined in accordance with NC-3922.3(a) for the thickness to radius ratio involved

FIG. NC-3922.1-2 REDUCTION OF DESIGN STRESSES REQUIRED TO ALLOW FOR
BIAXIAL STRESSES OF OPPOSITE SIGN

FIG. NC-3922.1-2 REDUCTION OF DESIGN STRESSES REQUIRED TO ALLOW FOR BIAxIAL STRESSES OF OPPOSITE SIGN

$$S_{cs} = 15,000$$

However, the values of S_{cs} calculated as above, but with R taken as equal to R_1 when the compressive unit force under consideration is latitudinal or with R taken as equal to R_2 when the compressive unit force is meridional, form the basis for the rules given in (b), (c), and (d) below for walls of double curvature.

(b) If both the meridional and latitudinal unit forces T_1 and T_2 are compressive and of equal magnitude, the computed compressive stress S_{cc} shall not exceed a value S_{ca} established for the applicable thickness-radius ratio as follows:

for $(t - c)/R$ values less than 0.00667:

$$S_{ca} = 1,000,000 (t - c)/R$$

for $(t - c)/R$ values between 0.00667 and 0.0175:

$$S_{ca} = 5650 + 154,200 (t - c)/R$$

for $(t - c)/R$ values greater than 0.0175:

$$S_{ca} = 8340$$

(c) If both the meridional and latitudinal unit forces T_1 and T_2 are compressive but of unequal magnitude, both the larger and the smaller computed compressive stresses shall be limited to values which satisfy the following requirements:⁴⁵

$$\frac{(\text{larger stress}) + 0.8 (\text{smaller stress})}{S_{cs} \text{ determined using } R \text{ for the larger unit force}} \leq 1.0$$

$$\frac{1.8 (\text{smaller stress})}{S_{cs} \text{ determined using } R \text{ for the smaller unit force}} \leq 1.0$$

(d) If the meridional unit force T_1 is compressive and the coexistent unit force T_2 is tensile, or if T_2 is compressive and T_1 is tensile, the computed compressive stress S_{cc} shall not exceed a value of S_{ca} determined from Fig. NC-3922.1-1 by entering the computed value of N and the value of $(t - c)/R$ associated with the compressive unit stress, and reading the value of S_c which corresponds to that point. Such value of S_c will be the limiting value of S_{ca} for the given conditions.

⁴⁵ In these expressions if the unit force is latitudinal, R shall be considered to be R_1 and, if meridional, R shall be considered as equal to R_2 .

Section F.1 of Appendix F of API 620 Feb. 1970 Ed. gives examples illustrating the determination of allowable compressive stress values S_{ca} .

NC-3922.4 Maximum Shearing Stresses.

The maximum shearing stresses in welds used for attaching manways, nozzles, reinforcements, or other attachments to the walls of a tank, and in sections of manway or nozzle necks serving as reinforcement attachment, shall not exceed 80% of the applicable maximum allowable tensile stress value S_{ts} .

NC-3923 Maximum Allowable Stress Values for Structural Members

NC-3923.1 General Stress Limits.

Subject to the provisions of NC-3923.2(c), the maximum stresses in internal or external diaphragms, webs, trusses, columns, and other framing, as determined for any loadings, shall not exceed the applicable allowable stresses given in Table NC-3923.1-1.

NC-3923.2 Slenderness Ratio Limits.

The slenderness ratio (the ratio of the unbraced length l to the least radius of gyration r) for structural members in compression and for tension members other than rods shall not exceed the following values, except as provided in (a) below:

	Maximum l/r
For main compression members	120
For bracing and other secondary members in compression	200
For main tension members	240
For bracing and other secondary members in tension	300

(a) The slenderness ratio of main compression members inside of a tank may exceed 120, but not 200, provided the member is not ordinarily subject to shock or vibration loads and the unit stress under full Design Loadings does not exceed the following fraction of the stress value given in Table NC-3923.1-1 for the member's actual l/r ratio:

$$f = 1.6 - \frac{l}{200r}$$

(b) The gross and net sections of structural members shall be as determined in (1) through (5) below.

(1) The gross section of a member at any point shall be determined by summing the products of the thickness and the gross width of each element as measured normal to the axis of the member. The net

Page 209

section shall be determined by substituting for the gross width the net width which, in the case of a member having a chain of holes extending across it in any diagonal or zigzag line, shall be computed by deducting from the gross width the sum of the diameters of all holes in the chain and adding, for each gage space in the chain, the following quantity:

$$\frac{s^2}{4g}$$

Pages 210-211

TABLE NC-3923.1-1
MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

	Column 1 For Members Not Subject to Pressure-Imposed Loads, ksi	Column 2 For Internal Members Resisting Pressure, ksi

NOTES:

(1) Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(2) All values for butt welds in tension or shear shall be multiplied by the applicable joint efficiency. These values are obtained by combining the following: a factor of 80% for shear strength of weld metal; an efficiency factor of approximately 85% for fillet welds or 80% for plug welds and slot welds; and a factor of 100% for perpendicular loading or approximately 75% for parallel loading.

TABLE NC-3923.1-1 (CONT'D) MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

where

s = longitudinal spacing (pitch), in., of any two successive holes
 g = transverse spacing (gage), in., of the same two holes

(2) In the case of angles, the gage for holes in opposite legs shall be the sum of the gages from the back of the angle less the thickness.

(3) In determining the net section across plug or slot welds, the weld metal shall not be considered as adding to the net area.

(4) For splice members, the thickness considered shall be only that part of the thickness of the member which has been developed by the welds or other attachments beyond the section considered.

(5) In pin connected tension members other than forged eyebars, the net section across the pinhole, transverse to the axis of the member, shall not be less than 135%, and the net section beyond the pinhole, parallel to the axis of the member, shall not be less than 90% of the net section of the body of the member. The net width of a pin connected member across the pinhole, transverse to the axis of the member, shall not exceed eight times the thickness of the member at the pin, unless lateral buckling is prevented.

(c) External structural or tubular columns and framing subject to stresses produced by a combination of wind and other applicable loads specified in NC-3921.4 may be proportioned for unit stresses 25% greater than those specified in Table NC-3923.1-1, provided the section thus required is not less than that required for all other applicable loads combined on the basis of the unit stresses specified in Table NC-3923.1-1. A corresponding increase may be applied to the allowable unit stresses in the connecting bolts or welds.

NC-3930 DESIGN PROCEDURE

NC-3931 Design of Tank Walls

(a) Free body analyses shall be made at successive levels from the top to the bottom of the tank for the purpose of determining the magnitude and character of the meridional and latitudinal unit forces which will exist in the walls of the tank at critical levels under

Page 212

all the various combinations of gas pressure or partial vacuum and liquid head to be encountered in service which may have a controlling effect on the design. To this end it will sometimes be necessary to make several analyses at a given level of the tank to establish the governing conditions of gas pressure and liquid head for that level. The thicknesses required in the main walls of the tank shall then be computed by the applicable procedures given in NC-3932.3.

(b) For tanks having points of marked discontinuity in the direction of the meridional tangent, such as occur at the juncture between a conical or dished roof or bottom and a cylindrical sidewall or at the juncture between a conical reducer and a cylindrical sidewall, the portions of the tank near such points shall be designed in accordance with the provisions of NC-3933.

NC-3932 Design of Sidewalls, Roofs, and Bottoms

NC-3932.1 Nomenclature.

The symbols used are defined as follows:

P	$= P_L + P_G$ = total pressure, psi, acting at a given level of the tank under a particular condition of loading
P_L	= pressure resulting from the liquid head at the level under consideration in the tank, psi
P_G	= gas pressure, psi, above the surface of the liquid. The maximum value, a pressure not exceeding 15 psig, is the nominal pressure rating of the tank. P_G is positive except in computations for investigating the ability of a tank to withstand a partial vacuum, where its value is negative.
T_1	= meridional unit force in the wall of the tank at the level under consideration, lb/in. of latitudinal arc. T_1 is positive when in tension.
T_2	= latitudinal unit force in the wall of the tank at the level under consideration, lb/in. of meridional arc. T_2 is positive when in tension. In cylindrical sidewalls the latitudinal unit forces are circumferential unit forces.
R_1	= radius of curvature of the tank wall in a meridian plane, at the level under consideration, in. R_1 is to be considered negative when it is on the opposite side of the tank wall from R_2 except as provided in NC-3932.2(f).
R_2	= length, in., of the normal to the tank wall at the level under consideration, measured from the wall of the tank to its axis of revolution. R_2 is always positive except as provided in NC-3932.2(f).
W	= total weight, lb, of that portion of the tank and its contents, either above the level under consideration, as in Fig. NC-3932.1-1 sketch (b) or below such level, as in Fig. NC-3932.1-1 sketch (a) which is treated as a free body in the

	computations for such level. W shall be given the same sign as P , when acting in the same direction as the pressure on the horizontal face of the free body, and the opposite sign when acting in the opposite direction.
F	= summation, lb, of the vertical components of the forces in all internal or external ties, braces, diaphragms, trusses, columns, skirts, or other structural devices or supports acting on the free body. F shall be given the same sign as P when acting in the same direction as the pressure on the horizontal face of the free body, and the opposite sign when acting in the opposite direction.
A_T	= cross-sectional area of the interior of the tank at the level under consideration, sq in.
S_{ts}	= maximum allowable stress for simple tension, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)
S_{ta}	= allowable tension stress, psi, as required in NC-3922.2(b)
S_{ca}	= allowable compression stress, psi, as required in NC-3922.3
S_{tc}	= calculated tension stress, psi, at the point under consideration
S_{cc}	= calculated compression stress, psi, at the point under consideration

NC-3932.2 Computation of Unit Forces

(a) At each level of the tank selected for free body analysis as specified in NC-3931 (Fig. NC-3932.1-1) and for each condition of gas and liquid loading which must be investigated at such level, the magnitude of the meridional and latitudinal unit forces in the wall of the tank shall be calculated from Eqs.⁴⁶ (1) and (2) below, except as provided in NC-3932.6 or NC-3933:

46 (a) Eq. (2) has been derived from a summation of the components, normal to the surface, of the T_1 and T_2 forces acting on a unit area of the tank wall subjected only to a pressure P . To be technically correct, the normal to the surface components of other loads, such as metal, snow, or insulation, should be added to or subtracted from the term P . For the usual internal Design Pressure, these added loads are small compared to the pressure P , and can be omitted without significant error. When the pressure P is relatively small, including the case of a partial vacuum loading, the other load components can have a substantial effect on the calculated T_2 force and the resultant thickness.

(b) Example F.3.01 in Appendix F of API 620 Feb. 1970 Edition calculates the required roof thicknesses under a small vacuum by considering the metal, insulation, and snow loads in Eqs. (1) through (4). The designer should note that if these loads had been omitted the calculated thicknesses would have been much less than the correct values.

(c) In Eqs. (1), (3), (6), and (8), the term W is intended to include loads, such as metal weight, of significant value. At points away from the vertical center line of the roof, the value of T_2 is required for the thickness calculations of Eqs. (16), (18), and (20), and the value of P in Eqs. (2), (4), and (7) must be modified by the normal components of the added loads for the correct determination of T_2 .

$$T_1 = \frac{R_2}{2} \left(P + \frac{W + F}{A_T} \right) \quad (1)$$

$$\begin{aligned} T_2 &= R_2 \left(P - \frac{T_1}{R_1} \right) \\ &= R_2 \left[P \left(1 - \frac{R_2}{2R_1} \right) - \frac{R_2}{2R_1} \left(\frac{W + F}{A_T} \right) \right] \end{aligned} \quad (2)$$

(1 - 2)

(b) Positive values of T_1 and T_2 indicate tensile forces and negative values indicate compressive forces.

(c) It will usually be necessary to make such analyses at the level of each horizontal joint in the sidewalls, roof, and bottom of the tank and at any intermediate levels at which the center of curvature changes significantly. Moreover, the maximum total pressure, liquid head plus gas pressure which can exist at a given level will not necessarily be the governing condition for that level; sufficient analyses shall be made at each level to establish that combination of liquid head and gas pressure or partial vacuum which, in conjunction with the allowable tensile and compressive stresses, will control the design at such level. Even though a tank may normally be operated at a fixed height of liquid contents, it shall be made safe for any conditions which might develop in filling or emptying the tank.

(d) The values for a point at a horizontal distance x from the vertical axis of a roof or bottom in which the length of the horizontal semiaxis a is two times the length of the vertical semiaxis b may be determined by multiplying the length a by the factor from Table NC-3932.2(d)-1. Values for ellipsoidal shapes of other proportions shall be calculated from the following equations:

$$R_1 = \frac{b^2}{a^4} \left[\frac{a^4}{b^2} + \left(1 - \frac{a^2}{b^2} \right) x^2 \right]^{3/2} = \frac{b^2 (R_2)^3}{a^4}$$

$$R_2 = \left[\frac{a^4}{b^2} + \left(1 - \frac{a^2}{b^2} \right) x^2 \right]^{1/2}$$

(e) Equations (1) and (2) are general equations applicable to any tank having a single vertical axis of revolution and to any free body which is isolated by a horizontal plane which intersects the walls of the tank in only one circle [NC-3932.2(f)]. For shapes most commonly used, these equations reduce to the simplified equations given in (1) through (3) below for the respective shapes indicated.

(1) For a spherical tank or spherical segment of a tank:

$R_1 = R_2 = R_s$, the spherical radius of the tank or segment, and Eqs. (1) and (2) become:

$$T_1 = \frac{R_s}{2} \left(P + \frac{W+F}{A_T} \right) \quad (3)$$

$$T_2 = R_s P - T_1 \quad (4)$$

(3 - 4)

If the sphere is for gas pressure only and if $W+F/A_T$ is negligible as compared with P_G Eqs. (3) and (4) reduce to:

$$(5) T_1 = T_2 = \frac{1}{2} P_G R_s$$

(2) For a conical roof or bottom:

$$R_1 = \text{infinity, and } R_2 = \frac{R_3}{\cos \alpha}$$

where

R_3

= horizontal radius of the base of the cone at the level under consideration, in.

α

= one-half the included apex angle of the conical roof or bottom

For this condition, Eqs. (1) and (2) reduce to:

$$T_1 = \left(\frac{R_3}{2 \cos \alpha} \right) \left(P + \frac{W + F}{A_T} \right) \quad (6)$$

$$T_2 = \frac{PR_3}{\cos \alpha} \quad (7)$$

(6 - 7)

(3) For cylindrical sidewalls of a vertical tank:

$R_1 = \text{infinity}$, and $R_2 = R_c$, the radius of the cylinder, and Eqs. (1) and (2) become:

$$T_1 = \frac{R_c}{2} \left(P + \frac{W + F}{A_T} \right) \quad (8)$$

$$T_2 = PR_c \quad (9)$$

(8 - 9)

If the cylinder is for gas pressure only, and if $W+F/A_T$

Page 214

is negligible as compared with P_G Eqs. (8) and (9) reduce to:

$$(10) T_1 = \frac{1}{2} P_G R_c$$

$$(11) T_2 = P_G R_c$$

$R_1 = u\alpha$

$R_2 = v\alpha$

TABLE NC-3932.2(d)-1 FACTORS FOR DETERMINING VALUES OF R_1 AND R_2 FOR 2:1 ELLIPSOIDAL ROOFS AND BOTTOMS

(f) In the case of a torispherical head shown in Fig. NC-3932.1-1(d), applicable equations for the meridional and latitudinal unit forces in the walls of the segment are as in Eqs. (12) and (13):

$$(12) T_1 = (\text{in preparation})$$

$$(13) T_2 = (\text{in preparation})$$

NC-3932.3 Required Thickness.

The thickness of the tank wall at any given level shall be not less than the largest value of t as determined for the level by the methods prescribed in (a) through (d) below. In addition, provision shall be made by means of additional metal, where needed, for the loadings other than internal pressure or possible partial vacuum enumerated in NC-3921.4 and if the tank walls have points of marked discontinuity in the direction of the meridional tangent, such as occur at the juncture between a conical or dished roof or bottom and a cylindrical sidewall, the portions of the tank near such points shall be designed in accordance with the provisions of NC-3933.

(a) If the unit forces T_1 and T_2 are both positive for the governing combination of gas pressure or partial vacuum and liquid head at a given level of the tank, the larger of the two shall be used for computing the thickness required at such level, as follows:

$$t = \frac{T_1}{S_{ts}} + c \quad \text{or} \quad t = \frac{T_2}{S_{ts}} + c \quad (14)$$

(14)

(b) If the unit force T_1 is positive and T_2 is negative for the governing combination of gas pressure or partial vacuum and liquid head at a given level of the tank, or if T_2 is positive and T_1 is negative, the thickness of tank wall required for this condition shall be determined by assuming different thicknesses until one is found for which the simultaneous values of the calculated tension stress S_{tc} and the calculated compression stress S_{cc} satisfy the requirements of NC-3922.2 (b) and NC-3922.3(d), respectively. The determination of this thickness will be facilitated by using a graphical solution such as illustrated in Appendix F, Section F.2 of API Standard 620, Feb. 1970 Edition. If the unit force acting in compression does not exceed 5% of the coexistent tensile unit force acting perpendicular to it, the designer may determine the thickness required for this condition by using the method specified in (a) above.

(c) If the unit forces T_1 and T_2 are both negative and are of equal magnitude for the governing condition of loading at a given level of the tank, the thickness of tank wall required shall be calculated using:

$$t = \frac{T_1}{S_{ca}} + c = \frac{T_2}{S_{ca}} + c \quad (15)$$

(15)

where S_{ca} has the appropriate value for the thickness-radius ratio, as required in NC-3922.3(b).

(d) If the unit forces T_1 and T_2 are both negative, but of unequal magnitude, for the governing condition of loading at a given level, the thickness of tank wall required for this condition shall be the largest of those

Page 216

thickness values, calculated by the following procedure, which show a proper correlation with the respective thickness-radius ratios involved in their calculation (Steps 2 and 4).

Step 1: Calculate the values of

$$t = \frac{\sqrt{(T' + 0.8T'')R'}}{1342} + c \quad (16)$$

(16)

and

$$t = \frac{\sqrt{T' R''}}{1000} + c \quad (17)$$

(17) using values of T' equal to the larger of the two coexistent unit forces, T'' equal to the smaller of the two unit forces, and taking R' and R'' as equal to R_1 and R_2 , respectively, if the larger unit force is latitudinal; but, conversely, taking R' and R'' as equal to R_2 and R_1 , respectively, if the larger unit force is meridional.

Step 2: Deduct the corrosion allowance from each of the two thicknesses calculated in Step 1 and check the thickness-radius ratio $(t - c)/R$ for each based on the value of R used in Eq. (16) or (17). If both thickness-radius ratios are less than 0.00667, the larger of the two thicknesses calculated in Step 1 will be the required thickness for the condition under consideration. Otherwise, proceed with Step 3.

Step 3: If one or both thickness-radius ratios determined in Step 2 exceed 0.00667, calculate the values of

$$t = \frac{T' + 0.8T''}{15,000} + c \quad (18)$$

(18)

and

$$t = \frac{T''}{8340} + c \quad (19)$$

(19)

Step 4: Deduct the corrosion allowance from each of the two thicknesses calculated in Step 3 and check the thickness-radius ratio $(t - c)/R$ for each using a value of R equal to R' as defined in Step 1 in connection with the thickness determined from Eq. (18) and a value of R equal to R_{dp} in connection with the thickness determined from Eq. (19). If both such thickness-radius ratios are greater than 0.0175, the larger of the two thicknesses calculated in Step 3 will be the required thickness for the condition under consideration. Otherwise, proceed with Step 5.

Step 5: If one or more of the thickness-radius ratios determined in Step 2 or Step 4 fall between 0.00667 and 0.0175 and the thickness involved was calculated by Eq. (16) or (18), find a thickness which satisfies the following equation:

$$\frac{10,150 (t - c) + 277,400 (t - c)^2}{R'} = T' + 0.8T'' \quad (20)$$

(20)

or, if the thickness involved was calculated by Eq. (17) or (19), find a thickness which satisfies the following equation:

$$\frac{5,650 (t - c) + 154,200 (t - c)^2}{R''} = T'' \quad (21)$$

(21)

Step 6: Make a selection of thickness from the values calculated. Calculate the values of S_{cc} for both T_1 and T_2 and check that the values of S_{cc} satisfy the requirements of NC-3922.3(c). Adjustment in the thickness may be required to make the values of S_{cc} satisfy the requirements of NC-3922.3(c).

NOTE: The procedure described in NC-3932.3(d) is predicated on the assumption that the problem is one in which biaxial compression with unit forces of unequal magnitude is the governing condition. In many cases, however, a tentative thickness will have been established previously by other design considerations and only needs to be checked for the external pressure or partial vacuum condition. In such cases, the problem is greatly simplified because the designer has only to calculate the values of S_{cc} for both T_1 and T_2 and then check to see that these values satisfy the requirements of NC-3922.3(c), as specified in Step 6 [see Section F.3 of Appendix I of API Standard 620 Feb. 1970 Edition, for examples illustrating the application of NC-3932.3(a)].

NC-3932.4 Least Permissible Thickness.

In no event shall the net thickness after fabrication of any plate subject to pressure imposed membrane stresses be less than $\frac{3}{16}$ in., exclusive of corrosion allowance. For tanks having cylindrical sidewalls with diameters from 60 ft up to but not including 120 ft, such thickness for sidewall plates shall not be less than $\frac{1}{4}$ in. exclusive of corrosion allowance.

NC-3932.5 External Pressure Limitations.

The thickness computed by the formulas and procedures specified in NC-3932, using a negative value of P_G equal to the partial vacuum for which the tank is to be designed, will ensure stability against collapse for tank surfaces of double curvature in which the meridional radius R_1 is equal to or less than R_2 or does not exceed R_2 by more than a very small amount. Data on the stability of sidewall surfaces of prolate spheroids are lacking and it is not intended that the equations and procedures be used for evaluating the stability of such surfaces or of cylindrical surfaces against external pressure. However, cylindrical sidewalls of vertical tanks designed in accordance with these rules for storage

Page 217

of liquids,⁴⁷ with the thickness of upper courses not less than specified in NC-3932.4 for the size of tank involved and with increasing thicknesses from top to bottom as required for the combined gas and liquid loadings, may safely be

subjected to a partial vacuum in the gas or vapor space not exceeding 1 oz/sq in.⁴⁸ with the operating liquid level in the tank at any stage from full to empty.

NC-3932.6 Special Considerations Applicable to Bottoms Resting Directly on Foundations

(a) *Uplift Considerations.* In the case of tanks with cylindrical sidewalls and flat bottoms, the uplift⁴⁹ from the pressure acting on the underside of the roof must not exceed the weight of the sidewalls plus the weight of that portion of the roof which is carried by the sidewalls when no uplift exists, unless such excess is counteracted by increasing the magnitude of the downward acting forces. This shall be a matter of agreement between the Certificate Holder and Owner. Similar precautions shall be taken with flat bottomed tanks of other shapes. All weights used in such calculations shall be based on net thicknesses of the materials, exclusive of corrosion allowance.

(b) *Foundation Considerations.* The type of foundation used for supporting the tank shall be taken into account in the design of bottom plates and welds. For recommended practice for construction of foundations, see API Standard 620, Feb. 1970 Edition, Appendix C.

NC-3933 Design of Roof and Bottom Knuckle Regions and Compression Rings

NC-3933.1 Nomenclature.

The symbols used are defined as follows:

w_h	= width, in., of the roof or bottom plate considered to participate in resisting the circumferential force acting on the compression ring region
w_c	= corresponding width, in., of the participating sidewall plate
t_h	= thickness, in., of the roof or bottom plate at and near the juncture of the roof or bottom and sidewalls, including corrosion allowance

⁴⁷ These rules do not contain provisions in respect to the design of cylindrical sidewalls subject to partial internal vacuum in tanks constructed for storage of gases or vapors alone.

⁴⁸ The vacuum relief valve or valves shall be set to open at a smaller partial vacuum so that the 1 oz/sq in. partial vacuum will not be exceeded when the inflow of air or gas through the valves is at its maximum specified rate.

⁴⁹ If external anchor bolts are used for resisting such uplift, it is recommended that their nominal diameter be not less than 1 in. plus a corrosion allowance of at least $\frac{1}{4}$ in. on the diameter.

t_c	= corresponding thickness, in., of the cylindrical sidewalls at and near such juncture
R_2	= length, in., of the normal to the roof or bottom at the juncture between the roof or bottom and the sidewalls, measured from the roof or bottom to the tank's vertical axis of revolution
R_c	= horizontal radius, in., of the cylindrical sidewall at its juncture with the roof or bottom
T_1	= meridional unit force in the roof or bottom of the tank at its juncture with the sidewall, lb/in. of circumferential arc
T_2	= corresponding latitudinal unit force ⁵⁰ in the roof or bottom, lb/in. of meridian arc
T_{2s}	= circumferential unit force ⁵⁰ in the cylindrical sidewall of the tank at its juncture with the roof or bottom, lb/in., measured along an element of the cylinder

α	= angle between the direction of T_1 and a vertical line. In a conical surface it is also one-half of the total vertex angle of the cone.
Q	= total circumferential force, lb, acting on a vertical cross section through the compression ring region
A_c	= net area, sq in., of the vertical cross section of metal required in the compression ring region, exclusive of all corrosion allowances
S_{ts}	= maximum allowable stress value for simple tension, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)

NC-3933.2 General Requirements.

When the roof or bottom of a tank is a cone or partial sphere and is attached to cylindrical sidewalls, the membrane stresses in the roof or bottom act inward on the periphery of the sidewalls. This results in circumferential compressive forces at the juncture, which shall be resisted either by a knuckle curvature in the roof or bottom or by a limited zone at the juncture of the intersecting roof or bottom plates and sidewall plates, supplemented in some cases by an angle, a rectangular bar, or a ring girder.

50 These forces are computed by the applicable equations in NC-3932

NC-3933.3 Requirements for Knuckle Regions

(a) If a curved knuckle is provided, a ring girder or other form of compression ring shall not be used and there shall be no sudden changes in the direction of a meridional line at any point. In addition, the radius of curvature of the knuckle in a meridional plane shall not be less than 6%, and preferably not less than 12%,

Page 218

of the diameter of the sidewalls.⁵¹ Subject to the provisions of (b) below, the thickness of the knuckle at all points shall satisfy the requirements of NC-3932.

FIG. NC-3933.4(a)-1 COMPRESSION RING REGION

FIG. NC-3933.4(a)-1 COMPRESSION RING REGION

(b) Application of the equations in NC-3932.2 to levels immediately above and below a point where two surfaces of differing meridional curvature have a common meridional tangent, as at the juncture between the knuckle region and the spherically dished portion of a torispherical roof, will result in the calculation of two latitudinal unit forces, differing in magnitude and possibly in sign, at the same point. The latitudinal unit force at such a point will be between the two calculated values, depending on the geometry of the tank wall in that area.

NC-3933.4 Requirements for Compression Rings

(a) If a curved knuckle is not provided, forces shall be resisted by other means in the compression ring region of the tank walls. The zone of the tank walls at the juncture between the roof or bottom and the sidewalls includes that width of plate on each side of the juncture which is considered to participate in resisting these forces [Fig. NC-3933.4(a)-1]. The thickness of the wall plate on either side of the juncture shall not be less than the thickness needed to satisfy the requirements of NC-3932, and the widths of plate making up the compression ring region shall be computed from the following equations:

51 Use of a knuckle radius as small as 6% of the sidewall diameter will frequently require an excessively heavy thickness for the knuckle region. The thickness requirements for such region will be found more reasonable if a larger knuckle radius is used.

$$w_h = 0.6 \sqrt{R_2 (t_h - c)} \quad (22)$$

$$w_c = 0.6 \sqrt{R_c (t_c - c)} \quad (23)$$

(22 - 23)

(b) The magnitude of the total circumferential force acting on any vertical cross section through the compression ring region shall be computed as follows:

$$(24) Q = T_2 w_h + T_2 w_c - T_1 R_c \sin \alpha$$

and the net cross-sectional area provided in the compression ring region shall not be less than that found to be required by the following equation:

$$A_c = \frac{Q}{15,000} \quad \text{or} \quad \frac{Q}{S_{ts}} \quad (25)$$

(25) depending on whether the value of Q as determined by Eq. (24) is negative⁵² or positive.

NC-3933.5 Details of Compression Ring Regions

(a) If the force Q is negative, indicating compression, the horizontal projection of the effective compression ring region shall have a width in a radial direction not less than 0.015 times the horizontal radius of the tank wall at the level of the juncture between the roof or bottom and the sidewalls. If such projected width does not meet this requirement, appropriate corrective measures shall be taken as specified in this subparagraph.

⁵² Because of the discontinuities and other conditions found in a compression ring region, biaxial stress design criteria are not considered applicable for a compressive force determined as in Eq.

(24). Experience has shown that a compressive stress of the order of 15.0 ksi as indicated in Eq. (25), is permissible in this case, provided the requirements of NC-3933.5 are satisfied.

(b) Whenever the circumferential force Q determined in accordance with NC-3933.4 is of such magnitude that the area required by Eq. (25) is not provided in a compression ring region with plates of the minimum thicknesses established by the requirements of NC-3932, or when Q is compressive and the horizontal projection of the width w_h is less than specified in NC-3933.5(a), the compression ring region shall be reinforced either by thickening the roof or bottom and

sidewall plates as required to provide a compression ring region having the necessary cross-sectional area and width as determined on the basis of the thicker

plates,⁵³ or by adding an angle, a rectangular bar, or a ring girder at the juncture of the roof or bottom and sidewall plates, or by a combination of these alternatives.

(c) An angle, bar, or ring girder, if used, may be located either inside or outside of the tank⁵⁴ and shall have a cross section of such dimensions that:

(1) its area makes up the deficiency between the area A_c required by Eq. (25), and the cross-sectional area provided by the compression ring region in the walls of the tank;

(2) the horizontal width of the angle, bar, or ring girder is not less than 0.015 times the horizontal radius R_c of the tank wall at the level of the juncture of the roof or bottom and the sidewalls, except that, when the cross-sectional area to be added in an angle or bar is not more than one-half of the total area required by Eq. (25), the width requirement for this member may be disregarded, provided the horizontal projection of the width w_h of participating roof or bottom plates alone is equal to or greater than $0.015R_c$ or, with an angle or bar located on the outside of a tank, the sum of the projection of the width w_h and the horizontal width of the added angle or bar is equal to or greater than $0.015R_c$.

(3) when bracing must be provided as specified in NC-3933.5(h), the moment of inertia of the cross section about a horizontal axis shall be not less than that required by Eq. (26).

53 Note that, unless the effect of the unit forces T_2 and T_3 on the resulting increments in width of participating plate may safely be neglected, the use of thicker plates involves recomputing not only w_h and w_c but also Q and A_c for the increased plate thicknesses; hence, the design of the compression ring region in this case resolves into a trial and error procedure.

54 See Fig. NC-3933.5(d)-1 for some acceptable details of construction of compression rings.

(d) When the vertical leg of an angle ring or a vertical flange of a ring girder is located on the sidewall of the tank, it may be built into the sidewall if its thickness is not less than that of the adjoining wall plates. However, if this construction is not used, the leg, edge, or flange of the compression ring next to the tank shall make contact with the wall of the tank around the entire circumference and, except as provided in (e) below, shall be attached along both the top and bottom edges by continuous fillet welds. These welds shall be of sufficient size to transmit the portion, Q_p , of the total circumferential force Q , to the compression ring angle, bar, or girder, assuming, in the case of welds separated by the width of a leg or flange of a structural member as shown in Fig. NC-3933.5(d)-1 sketches (a) and (d), that only the weld nearest the roof or bottom is effective. The part thicknesses and weld sizes in Table NC-4247.6(d)-1 relate to dimensions in the as-welded condition before deduction of corrosion allowances, but all other part thicknesses and weld sizes referred to, in this subparagraph, relate to dimensions after deduction of corrosion allowance.

(e) If a continuous weld is not needed for strength or as a seal against corrosive elements, attachment welds along the lower edge of a compression ring on the outside of a tank may be intermittent, provided:

(1) the summation of their lengths is not less than one-half the circumference of the tank;

(2) the unattached width of tank wall between the ends of welds does not exceed eight times the tank wall thickness exclusive of corrosion allowance;

(3) the welds are of such size as needed for strength but in no case smaller than specified in Table NC-4247.6(d)-1.

(f) The projecting part of a compression ring shall be placed as close as possible to the juncture between the roof or bottom plates and the sidewall plates.

(g) If a compression ring on either the inside or outside of a tank is of such shape that liquid may be trapped, it shall be provided with adequate drain holes uniformly distributed along its length. Similarly, if the shape of a compression ring on the inside of a tank is such that gas would be trapped on the underside thereof when the tank is being filled with liquid, adequate vent holes shall be provided along its length. Where feasible, such drain or vent holes shall be not less than $\frac{3}{4}$ in. (19 mm) in diameter.

(h) The projecting part of a compression ring without an outer vertical flange need not be braced, provided the width of such projecting part in a radial vertical plane does not exceed 16 times its thickness. With this exception, the horizontal part of the compression ring shall be braced at intervals around the circumference of the tank with brackets or other

suitable members securely attached to both the ring and the tank wall to prevent such part of the ring from buckling laterally. When such bracing is required, the moment of inertia of the cross section of the angle, bar, or ring girder about a horizontal axis shall be not less than that calculated to be required by the following equation:⁵⁵

$$I_1 = \frac{1.44 Q_p R_c^2}{29,000,000 k} = 5 \frac{Q_p R_c^2}{k} \times 10^{-8} \quad (26)$$

(26)

where

I_1

= required moment of inertia, in.⁴, for the cross section of a steel compression ring with respect to a horizontal axis through the centroid of the section, not taking credit for any portion of the tank wall, except that, in the case of an angle ring whose vertical leg is attached to or forms a part of the tank wall, the moment of inertia of only the horizontal leg shall be considered, and it shall be figured with respect to a horizontal axis through the centroid of such leg⁵⁴

⁵⁵ Note that the value required for I as calculated from Eq. (26) is not applicable for materials other than steel.

Q_p

= that portion of the total circumferential force Q , lb, [Eq. (24)] which is carried by the compression ring angle, bar, or girder, as computed from the ratio of the cross-sectional area of the compression ring to the total area of the compression zone

R_c

= horizontal radius, in., of the cylindrical sidewall of the tank at its juncture with the roof or bottom

k

= a constant whose value depends on the magnitude of the angle θ , subtended at the central axis of the tank by the space between adjacent brackets, or other supports, which value shall be determined from the following tabulation in which n is the number of brackets or other supports evenly spaced around the circumference of the tank

Some Values for k Based on n, θ

n	30	24	20	18	15	12
θ , deg.	12	15	18	20	24	30
k	186.6	119.1	82.4	66.6	45.0	29.1
n	10	9	8	6	5	4
θ , deg.	36	40	45	60	72	90
k	20.0	16.0	12.5	6.7	4.4	2.6

In no case shall θ be larger than 90 deg.

FIG. NC-3933.5(d)-1 PERMISSIBLE DETAILS OF COMPRESSION RING

FIG. NC-3933.5(d)-1 PERMISSIBLE DETAILS OF COMPRESSION RING

NC-3934 Nozzle Piping Transitions

The stress limits of Table NC-3921.6-1 shall apply to all portions of nozzles which lie within the limits

Page 221

of reinforcement given in NC-3334, except as provided in NC-3935. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of NC-3600.

NC-3935 Consideration of Standard Reinforcement

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of NC-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table NC-3921.6-1. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are to be designed for, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table NC-3921.6-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit specified for σ_m in Table NC-3921.6-1 for a given condition.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NC-4000

ARTICLE NC-4000 FABRICATION AND INSTALLATION

Page 223

NC-4100 GENERAL REQUIREMENTS

NC-4110 INTRODUCTION

(a) Components, parts, and appurtenances shall be fabricated and installed in accordance with the rules of this Article and shall be manufactured from materials which meet the requirements of NC-2000.

(b) Vessels designed to the requirements of NC-3200 shall meet the requirements of this Article except for NC-4240 and NC-4433. In this case, the requirements of NC-4260 apply.

(c) Atmospheric and 0-15 psig (0-103 kPa) storage tanks shall be fabricated in accordance with the rules of this Article.

NC-4120 CERTIFICATION OF MATERIALS AND FABRICATION BY COMPONENT CERTIFICATE HOLDER

NC-4121 Means of Certification

The Certificate Holder for an item shall certify, by application of the appropriate Code symbol and completion of the appropriate Data Report in accordance with NCA-8000, that the materials used comply with the requirements of NC-2000 and that the fabrication or installation complies with the requirements of this Article.

NC-4121.1 Certification of Treatments, Tests, and Examinations.

If the Certificate Holder or Subcontractor performs treatments, tests, repairs, or examinations required by other Articles of this Subsection, the Certificate Holder shall certify that this requirement has been fulfilled (NCA-3862). Reports of all required treatments and of the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

NC-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication or installation of the item the material is subjected to heat treatment that has not been covered by treatment of the test coupons (NC-2200) and that may reduce either tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of NC-2000.

NC-4121.3 Repetition of Surface Examination After Machining.

During the fabrication or installation of an item, if materials for pressure containing parts are machined, then the Certificate Holder shall reexamine the surface of the material in accordance with NC-2500 when:

(a) the surface was required to be examined by the magnetic particle or liquid penetrant method in accordance with NC-2500; and

(b) the amount of material removed from the surface exceeds the lesser of $\frac{1}{8}$ in. (3.2 mm) or 10% of the minimum required thickness of the part.

NC-4122 Materials Identification

(a) Material for pressure retaining parts shall carry identification markings which will remain distinguishable until the component is assembled or installed. If the original identification markings are cut off or the material is divided, either the marks shall be transferred to the parts cut or a coded marking shall be used to ensure identification of each piece of material during subsequent fabrication or installation. In either case, an as-built sketch or a tabulation of materials shall be made identifying each piece of material with the Certified Material Test Report, where applicable, and the coded marking. For studs, bolts, nuts, and heat exchanger tubes, it is permissible to identify the Certified Material Test Reports for material in each component in lieu of identifying each piece of material with the

Page 230

Certified Material Test Report and the coded marking. Material supplied with a Certificate of Compliance and welding and brazing materials shall be identified and controlled so that they can be traced to each component or installation of a piping system, or else a control procedure shall be employed which ensures that the specified materials are used.

(b) Material from which the identification marking is lost shall be treated as nonconforming material until appropriate tests or other verifications are made and documented to assure material identification. Testing is required unless positive identification can be made by other documented evidence. The material may then be remarked upon establishing positive identification.

NC-4122.1 Marking Materials.

Material shall be marked in accordance with NC-2150.

NC-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with requirements of NC-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to NC-5100 and NC-5500, respectively, unless so specified.

NC-4125 Testing of Welding and Brazing Materials

All welding and brazing materials shall meet the requirements of NC-2400.

NC-4130 REPAIR OF MATERIAL

Material originally accepted on delivery in which defects exceeding the limits of NC-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used, provided the condition is corrected in accordance with the requirements of NC-2500 for the applicable product form, except that:

- (a) the limitation on the depth of the weld repair does not apply;
- (b) the time of examination of the weld repairs to weld edge preparations shall be in accordance with NC-5130;
- (c) radiographic examination is not required for weld repairs to seal membrane material when the material thickness is $\frac{1}{4}$ in. (6 mm) or less;
- (d) radiographic examination is not required for welded repairs in material used in storage tanks, provided that the welded joints in these materials are not required to be radiographed, the extent of the welded repair does not exceed 10 sq in. of the surface area, and the magnetic particle or liquid penetrant examination of the repair is made as required by NC-2539.4.

NC-4200 FORMING, CUTTING, AND ALIGNING

NC-4210 CUTTING, FORMING, AND BENDING

NC-4211 Cutting

Materials may be cut to shape and size by mechanical means, such as machining, shearing, chipping, or grinding, or by thermal cutting.

NC-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material, using preheat schedules such as suggested in Appendix D.

NC-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend pressure retaining materials, including weld metal, provided the required dimensions are attained (see NC-4214 and NC-4220), and provided the impact properties of the materials, when required, are not reduced below the minimum specified values, or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (56°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in NC-4213. When required, the process shall be qualified to meet thickness requirements as outlined in NC-4223.1.

NC-4213 Qualification of Forming Processes for Impact Property Requirements

When impact testing is required by the Design Specifications, a procedure qualification test shall be conducted using specimens taken from materials of the same specification, grade or class, heat treatment, and with similar impact properties, as required for the material in the component. These specimens shall be

Page 231

subjected to the equivalent forming or bending process and heat treatment as the material in the component. Applicable tests shall be conducted to determine that the required impact properties of NC-2300 are met after straining.

NC-4213.1 Exemptions.

Procedure qualification tests are not required for material listed in (a) through (f) below:

- (a) hot formed material, such as forgings, in which the hot forming is completed by the Material Manufacturer prior to removal of the impact test specimens;
- (b) hot formed materials represented by test coupons required in either NC-2211 or NC-4121.2 which have been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;
- (c) materials which do not require impacts in accordance with NC-2300;
- (d) materials which have a final strain less than 0.5%;
- (e) material where the final strain is less than that of a previously qualified procedure for that material;
- (f) material from which the impact testing required by NC-2300 is performed on each heat and lot, as applicable, after forming.

NC-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

- (a) The tests shall be performed on three different heats of material, both before straining and after straining and heat treatment, to establish the effects of the forming and subsequent heat treatment operations.
- (b) Specimens shall be taken in accordance with the requirements of NC-2000 and shall be taken from the tension side of the strained material.
- (c) The percent strain shall be established by the following equations:
for cylinders:

$$\% \text{ strain} = \frac{50t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

for spherical or dished surfaces:

$$\% \text{ strain} = \frac{75t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

for pipe:

$$\% \text{ strain} = \frac{100r}{R}$$

where

t	= nominal thickness, in.
R_f	= final radius to center line of shell, in.
R_o	= original radius (equal to infinity for a flat part), in.
R	= nominal bending radius to the center line of the pipe, in.
r	= nominal radius of the pipe, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient C_v test specimens shall be taken from each of the three heats of material to establish a transition curve showing both the upper and lower shelves. On each of the three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen for each shelf. Depending on the product form, it may be necessary to plot the transition curves using both the lateral expansion and energy level data (NC-2300). In addition, drop weight tests shall be made when required by NC-2300.

(f) Using the results of the impact test data from each of three heats, taken both before and after straining, determine either:

(1) the maximum change in NDT temperature along with:

(a) the maximum change of lateral expansion and energy at the temperature under consideration; or

(b) the maximum change in temperature at the lateral expansion and energy levels under consideration; or

(2) where lateral expansion is the acceptance criteria (NC-2300), either the maximum change in temperature or the maximum change in lateral expansion.

NC-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the component shall have impact properties, before forming, sufficient to

NC-4213.4 Requalification.

A new procedure qualification test is required when any of the changes in (a), (b), or (c) below are made.

(a) The actual postweld heat treatment time at temperature is greater than previously qualified considering NC-2211. If the material is not postweld heat treated, the procedure must be qualified without postweld heat treatment.

(b) The maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%.

(c) Where preheat over 250°F (121°C) is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

NC-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of NC-2124 and NC-3000, the material may be repaired in accordance with NC-4130.

NC-4220 FORMING TOLERANCES

NC-4221 Tolerance for Vessel Shells

Cylindrical, conical, or spherical shells of a completed vessel, except formed heads covered by NC-4222, shall meet the requirements of the following subparagraphs at all cross sections.

NC-4221.1 Maximum Difference in Cross-Sectional Diameters.

The difference in inches between the maximum and minimum diameters at any cross-section shall not exceed the smaller of $(D + 50)/200$ and $D/100$, where D is the nominal inside diameter, in., at the cross section under consideration. The diameters may be measured on the inside or outside of the vessel. If measured on the outside, the diameters shall be corrected for the plate thickness at the cross section under consideration (Fig. NC-4221.1-1). When the cross section passes through an opening, the permissible difference in inside diameters given herein may be increased by 2% of the inside diameter of the opening.

NC-4221.2 Maximum Deviation From True Theoretical Form for External Pressure.

Vessels designed for external pressure shall meet the tolerances given in (a) through (e) below.

(a) The maximum plus or minus deviation from the true circular form of cylinders or the theoretical form of other shapes, measured radially on the outside or inside of the component, shall not exceed the maximum permissible deviation obtained from Fig. NC-4221.2(a)-1. Measurements shall be made from a segmental circular template having the design inside or outside radius depending on where the measurements are taken and a chord length equal to twice the arc length obtained from Fig. NC-4221.2(a)-2. For Fig. NC-4221.2(a)-1, the maximum permissible deviation e need not be less than $0.3t$. For Fig. NC-4221.2(a)-2, the arc length need not be greater than $0.30D_o$. Measurements shall not be taken on welds or other raised parts.

FIG. NC-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

FIG. NC-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

(b) The value of t , in., at any cross section is the nominal plate thickness less corrosion allowance for sections of constant thickness and the nominal thickness of the thinnest plate less corrosion allowance for sections having plates of more than one thickness.

(c) The value of L in Figs. NC-4221.2(a)-1 and NC-4221.2(a)-2 is determined by (1), (2), and (3) below.

(1) For cylinders, L is as given in NC-3133.2.

(2) For cones, L is the axial length of the conical section if no stiffener rings are used or, if stiffener rings are used, the axial length from the head bend line at the large end of the cone to the first stiffener ring, with D_o taken as the outside diameter in inches of the cylinder at the large end of the cone.

(3) For spheres, L is one-half of the outside diameter D_o in.

(d) The dimensions of a completed vessel may be brought within the requirements by any process which will not impair the strength of the material.

(e) Sharp bends and flat spots shall not be permitted unless provision is made for them in the design.

NC-4221.3 Deviations From Tolerances.

Deviations from the tolerance requirements stipulated in NC-4221.1 and NC-4221.2 are permitted, provided the drawings are modified and reconciled with the design calculations.

FIG. NC-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

FIG. NC-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

NC-4221.4 Tolerance Deviations for Vessel Parts Fabricated From Pipe.

Vessel parts subjected to either internal or external pressure and fabricated from pipe, meeting all other requirements of this Subsection, may have variations of diameter and deviations from circularity permitted by the specification for such pipe.

NC-4221.5 Localized Thin Areas.

Localized thin areas are permitted if the adjacent areas surrounding each have sufficient thickness to provide the necessary reinforcement according to the rules for reinforcement in NC-3330.

NC-4222 Tolerances for Formed Vessel Heads

The tolerance for formed vessel heads shall be as set forth in the following subparagraphs.

NC-4222.1 Maximum Difference in Cross-Sectional Diameters.

The skirt or cylindrical end of a formed head shall be circular to the extent that the difference in inches between the maximum and minimum diameters does not exceed the lesser of $(D + 50)/200$ and $(D + 12)/100$, where D is the nominal inside diameter, in., and shall match the cylindrical edge of the adjoining part within the alignment tolerance specified in

NC-4222.2 Deviation From Specified Shape

(a) The inner surface of a torispherical or ellipsoidal head shall not deviate outside the specified shape by more than $1\frac{1}{4}\%$ of D , nor inside the specified shape by more than $\frac{5}{8}\%$ of D , where D is nominal inside diameter of the vessel. Such deviations shall be measured perpendicular to the specified shape and shall not be abrupt. The knuckle radius shall not be less than specified. For 2:1 ellipsoidal heads, the knuckle radius may be considered to be 17% of the diameter of the vessel.

FIG. NC-4221.2(a)-2 MAXIMUM ARC LENGTH FOR DETERMINING PLUS OR MINUS DEVIATION

FIG. NC-4221.2(a)-2 MAXIMUM ARC LENGTH FOR DETERMINATION PLUS OR MINUS DEVIATION

(b) Hemispherical heads and any spherical portion of a formed head shall meet the local tolerances for spheres as given in NC-4221.2, using L as the outside spherical radius in inches and D_o as 2 times L .

(c) Deviation measurements shall be taken on the surface of the base material and not on welds.

NC-4223 Tolerances for Formed or Bent Piping

The tolerances for formed or bent piping shall be as set forth in the following subparagraphs.

NC-4223.1 Minimum Wall Thickness

(a) In order to assure that the wall thickness requirements of the design calculations are met, the actual thickness shall be measured, or the process shall be qualified by demonstrating that it will maintain the required wall thickness.

(b) As an alternate to (a) above, the requirements of Table NC-3642.1(b)-1 shall be followed.

NC-4223.2 Ovality Tolerance.

Unless otherwise justified by the design calculations, the ovality of piping after bending shall not exceed 8% as determined by

$$100 \times (D_{\max} - D_{\min})/D_o$$

where

D_o = the nominal pipe outside diameter, in.

$D_{\min}$ = the minimum outside diameter after bending or forming, in.

$D_{\max}$ = the maximum outside diameter after bending or forming, in.

Page 235

NC-4224 Tolerances for Storage Tanks

The horizontal circular cross section of storage tanks shall be sufficiently true to round so that the difference between the maximum and minimum diameters measured inside or outside at any section in a cylindrical wall shall not exceed 1% of the average diameter or 12 in. (305 mm), whichever is less, measured 6 ft (1.8 m) or one plate width from the top and bottom juncture, respectively, if these junctures are of a type which offers serious restraint when the tank is filled or under the specified maximum vapor pressure. At any section in a sidewall having double curvature, this difference in diameter shall not exceed $\frac{1}{2}\%$ of the average diameter or 6 in., whichever is less.

NC-4224.1 Maximum Difference in Cross-Sectional Diameters for Tanks of Double Curvature.

For tanks of double curvature, the meridian curvature of the plate surface shall not deviate from the design shape by more than $\frac{1}{2}\%$ of the radius, measured radially, and shall not show abrupt changes. Plate surfaces shall merge smoothly into the adjoining surfaces in all directions. Local inward deviations, such as flat spots, shall be limited by NC-4224.2.

NC-4224.2 Local Inward Deviations.

Local inward deviations, such as flat spots, if present on wall or bottom surfaces having double curvature, shall not be greater than the plate thickness, and shall not have a diameter d greater than $\sqrt{8Rt}$, where R is the radius of the tank and t is the thickness of the plate involved. R shall be taken as R_1 , with d being the chord in a meridional direction, and as R_2 , with d being the chord in a latitudinal direction.

NC-4224.3 Tolerance Measurements.

The tolerance measurements are given for a tank while empty and shall be taken with a steel tape, making corrections for temperature, sag, and wind.

NC-4230 FITTING AND ALIGNING

NC-4231 Fitting and Aligning Methods

Parts that are to be joined by welding may be fitted, aligned, and retained in position during the welding operation by the use of bars, jacks, clamps, tack welds, or temporary attachments.

NC-4231.1 Tack Welds.

Tack welds used to secure alignment shall either be removed completely when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds removed.

GENERAL NOTE:

The weld end transitions are typical and are not intended as requirements. Refer to NC-4250 for weld end transition requirements.

FIG. NC-4233-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

TABLE NC-4232(a)-1 MINIMUM ALLOWABLE OFFSET IN FINAL WELDED JOINTS

NC-4232 Alignment Requirements When Components Are Welded From Two Sides

(a) Alignment of sections which are welded from two sides shall be such that the maximum offset of the finished weld will not be greater than the applicable amount listed in Table NC-4232(a)-1, where t is the nominal thickness of the thinner section at the joint.

(b) Joints in spherical vessels, joints within heads and joints between cylindrical shells and hemispherical heads shall meet the requirements in Table NC-4232(a)-1 for longitudinal joints.

NC-4232.1 Fairing of Offsets.

Any offset within the allowable tolerance provided above shall be faired to at least 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld.

NC-4233 Alignment Requirements When Inside Surfaces Are Inaccessible

(a) When the inside surfaces of items are inaccessible for welding or fairing in accordance with NC-4232, alignment of sections shall meet the requirements of (1) and (2) below.

(1)(a) For circumferential joints the inside diameters shall match each other within $\frac{1}{16}$ in. (1.6 mm) When the items are aligned concentrically, a uniform mismatch of $\frac{1}{32}$ in. (0.8 mm) all around the joint can result, as shown in Fig. NC-4233-1 sketch (a). However,

Page 236

other variables not associated with the diameter of the item often result in alignments that are offset rather than concentric. In these cases, the maximum misalignment at any one point around the joint shall not exceed $\frac{3}{32}$ in. (2.4 mm), as shown in Fig. NC-4233-1 sketch (b). Should tolerances on diameter, wall thickness, out-of-roundness, etc., result in inside diameter variation which does not meet these limits, the inside diameters shall be counterbored, sized, or ground to produce a bore within these limits, provided the requirements of NC-4250 are met.

GENERAL NOTE:

The weld end transitions are typical and are not intended as requirements. Refer to NC-4250 for weld end transition requirements.

FIG. NC-4233-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

FIG. NC-4233-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

(1)(b) Offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(2) For longitudinal joints the misalignment of inside surfaces shall not exceed $\frac{3}{32}$ in. (2.4 mm), and the offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(b) Single welded joints may meet the alignment requirements of (1) and (2) above in lieu of the requirements of NC-4232.

NC-4240 REQUIREMENTS FOR WELD JOINTS IN COMPONENTS¹

NC-4241 Category A Weld Joints in Vessels and Longitudinal Weld Joints in Other Components

Category A weld joints in vessels and longitudinal weld joints in other components shall be full penetration butt joints. Joints that have been welded from one side with backing that has been removed, and those welded from one side without backing, are acceptable as full penetration welds provided the weld root side of the joints meet the requirements of NC-4424.

NC-4242 Category B Weld Joints in Vessels and Circumferential Weld Joints in Other Components

Category B weld joints in vessels and circumferential weld joints in other components shall be full penetration butt joints, except that piping 2 in. nominal pipe size (DN 50) and smaller may be socket welded. Joints prepared with opposing lips to form an integral backing ring and joints with backing strips which are not later removed are acceptable, provided the requirements of NC-3352.2 are met.

¹ See NC-4246 and NC-4247 for special weld joint requirement in storage tanks

NC-4243 Category C Weld Joints in Vessels and Similar Weld Joints in Other Components

Category C weld joints in vessels and similar weld joints in other components shall be full penetration joints, as shown in Figs. NC-4243-1 and NC-4243-2, except that socket welded flanges of 2 in. nominal pipe size and less and slip-on flanges may be used.

NC-4243.1 Flat Heads and Tubesheets With Hubs.

Hubs for butt welding to the adjacent shell, head, or other pressure part, as in Fig. NC-4243.1-1, shall not be machined from rolled plate. The component having the hub shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material, in a direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen, subsize if necessary, taken in this direction and as close to the hub as is practical.² In no case shall the height of the hub be less than 1.5 times the thickness of the pressure part to which it is welded.

NC-4244 Category D Weld Joints in Vessels and Branch and Piping Connection Weld Joints in Other Components

Category D weld joints in vessels and similar weld joints in other components shall be welded using one of the details of (a) through (e) below.

(a) *Butt Welded Nozzles and Branch Piping Connections.* Nozzles and branch piping connections shall be attached by full penetration butt welds through the wall of the component, nozzle, or branch as shown in Fig. NC-4244(a)-1. Backing strips, if used, may be left in place.

(b) *Corner Welded Nozzles and Branch Piping Connections.* Nozzles and branch piping connections shall be joined to the component by full penetration welds through the wall of the component, nozzle, or branch similar to those shown in Fig. NC-4244(b)-1. When complete joint penetration cannot be verified by visual examination or other means permitted, backing strips or equivalent shall be used with full penetration welds deposited from only one side. Backing strips, if used, may be left in place.

2 One test specimen may represent a group of forgings, provided they are of the same nominal dimensions, from the same heat of material and the same heat treatment lot, and forged in the same manner.

(c) *Deposited Weld Metal of Opening for Nozzles and Branch Piping Connections.* Nozzles and branch

Page 238

piping connections shall be joined to the component by full penetration weld to built-up weld deposits applied to the component, nozzle, or branch as shown in Fig. NC-4244(c)-1. Backing strips, if used, may be left in place. Fillet welds shall be used only to provide a transition between the parts joined or to provide a seal. The fillet welds, when used, shall be finished by grinding to provide a smooth surface having a transition radius at its intersection with either part being joined.

FIG. NC-4243-1 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS
For Definitions of Nomenclature, See NC-3358.3(e)(1)

FIG. NC-4243-1 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS

FIG. NC-4243-2 ATTACHMENT OF PRESSURE PARTS TO PLATES TO FORM A CORNER JOINT
For Definitions of Nomenclature, See NC-3358.3(e)(2)

FIG. NC-4243-2 ATTACHMENT OF PRESSURE PARTS TO PLATES TO FORM A CORNER JOINT

(d) *Partial Penetration Welded Nozzles and Branch Piping Connections.* Partial penetration welds in components and branch piping connections, shall meet the weld design requirements of NC-3352.4(d) and NC-3359. Nozzles shall be attached as shown in Fig. NC-4244(d)-1. Reinforcing plates of nozzles attached to the outside of a vessel shall be provided with at least one telltale hole, maximum size $\frac{1}{4}$ in. pipe tap, that may be tapped for a preliminary compressed air and soapsuds test for tightness of welds. These telltale holes may be left open or may be plugged when the vessel is in service. If the holes are plugged, the plugging material used shall not be capable of sustaining pressure between the reinforcing plate and the vessel wall.

3 Written and illustrated with internal threads but also applicable to externally threaded and socket or butt welded fittings

(e) *Attachment of Fittings With Internal Threads.*³ Internally threaded fittings shall be attached by a full penetration groove weld or for 3 in. nominal pipe size (DN 80) and less, by two fillet or partial penetration welds, one on each face of the vessel wall, or by a fillet groove weld from the outside only as shown in Fig. NC-4244(e)-1 sketch (c-3). Internally threaded fitting and bolting pads not exceeding 3 in. nominal pipe size (DN 80), as shown in Fig. NC-4244(e)-2, may be attached to components having a wall thickness

not greater than $\frac{3}{8}$ in. (10 mm) by a fillet weld deposited from the outside only. The design requirements of NC-3352.4 (e) shall be met for all components.

NC-4245 Complete Joint Penetration Welds

Complete joint penetration is considered to be achieved when the acceptance criteria for the examinations specified by this Subsection have been met. No other examination is required to assess that complete penetration has been achieved.

NC-4246 Atmospheric Storage Tank Special Joints

Requirements for special joints for atmospheric storage tanks are given below.

NC-4246.1 Bottom Plates.

Bottoms shall be built to either one of the alternative methods of construction given in (a) and (b) below.

(a) Lap welded bottom plates shall be reasonably rectangular and square edged. Three plate laps in tank bottoms shall not be closer than 12 in. (305 mm) from each other and also from the tank shell. Bottom plates need be welded on the top side only with a continuous full fillet weld on all seams [Fig. NC-4246.1(a)-1]. The plates under the bottom ring shell connection shall have the outer ends of the joints fitted and lap welded to form a smooth bearing for the shell plates as shown in Fig. NC-4246.1(a)-1.

(b) Butt welded bottom plates shall have the parallel edges prepared for butt welding with either square or V-grooves. If square grooves are employed, the root opening shall be not less than $\frac{1}{4}$ in. The butt welds shall be made by applying a backing strip $\frac{1}{8}$ in. (3.2 mm) thick or heavier by tack welding to the underside of the plate [Fig. NC-4246.1(a)-1]. A metal spacer shall be used, if necessary, to maintain the root opening between the adjoining plate edges. The Certificate Holder may submit other methods of butt welding the bottom for the Owner's approval. Three plate joints in tank bottoms shall not be closer than 12 in. (305 mm) from each other and also from the tank shell.

NC-4246.2 Shell-to-Bottom Attachment.

The attachment between the bottom edges of the lowest course shell plate and the bottom plate shall be a continuous full wall thickness weld with a cover fillet on each side of shell plate [Fig. NC-4246.1(a)-1] or, for tanks not exceeding 35 ft (10.6 m) in diameter, the bottom plates may be flanged and butt welded to the bottom shell course. The flanged tank bottom plates shall be butt welded and have a thickness equal to the thickness of the bottom shell course. The inside radius of the bend shall be neither less than $1.75t$ nor more than $3t$.

NC-4246.3 Roof-to-Sidewall Attachment.

Roof plates shall be attached to the top angle of the tank with a continuous fillet weld on the top side only (Fig. NC-4246.3-1). Roof plates of supported cone roofs shall not be attached to the supporting members. For cone roofs the fillet weld shall be $\frac{3}{16}$ in. (4.8 mm) or smaller.

NC-4246.4 Roof Plates.

Roof plates shall be attached at least by a continuous full fillet lap joint on the top side (Fig. NC-4246.3-1). The top angle sections for self supporting roofs shall be joined by full penetration butt welds.

NC-4246.5 Nozzle, Manhole, and Bottom Outlet.

Nozzles, manholes, and outlets shall be attached by full fillet welds as shown in Figs. NC-4246.5-1 through NC-4246.5-4.

NC-4246.6 Flanges to Roof Nozzles, Manholes, and Bottom Outlets.

Flanges to roof nozzles, manholes, and bottom outlets shall be attached by fillet welds as shown in Figs. NC-4246.5-1, NC-4246.5-2, and NC-4246.5-4.

NC-4246.7 Special Requirements.

Special weld requirements for storage tanks are given in (a) through (d) below.

(a) The minimum size of fillet welds shall be as follows: plates $\frac{3}{16}$ in. (4.8 mm) thick, full fillet welds; plates over $\frac{3}{16}$ in. (4.8 mm) thick, not less than one-third the thickness of the thinner plate at the joint, with a minimum of $\frac{3}{16}$ in. (4.8 mm).

(b) Lap welded joints, as tack welded, shall be lapped not less than five times the nominal thickness of the thinner plate joined; but in the case of double welded lap joints the lap need not exceed 2 in. (51 mm), and in the case of single welded lap joints the lap need not exceed 1 in. (25 mm).

(c) For plates over $\frac{1}{2}$ in. (13 mm) thick in the sidewalls, roof, or bottom of the tank, if the thickness of two adjacent plates which are to be butt welded together differs more than $\frac{1}{8}$ in. (3.2 mm), the thicker plate shall be trimmed to a smooth taper extending for a distance at least three times the offset between the abutting surfaces so that the adjoining edges will be approximately the same thickness (Fig. NC-3361-1). The length of the required taper may include the width of the weld.

(d) Top angle sections for self-supporting roofs shall be joined by full penetration butt welds.

Page 241

Page 242

GENERAL NOTE:

Not permissible if machined from rolled plate. The tension test specimen may be located, when possible, inside the forged hub, instead of outside, as shown.

FIG. NC-4244(e)-1 SOME ACCEPTABLE TYPES OF WELDED NOZZLES

NC-4246.8 Other Weld Joints.

The fabrication requirements for weld joints not specifically covered by NC-4246, such as sidewall weld joints and nozzle-to-flange weld joints, are the same as given in NC-4240 for Category A, B, and C weld joints for vessels.

NC-4247 0-15 psi (0-103 kPa) Storage Tank Special Joints

Requirements for special joints for 0-15 psi (0-103 kPa) storage tanks are given below.

NC-4247.1 Bottoms.

All welds in flat bottoms supported directly on foundations shall be single full fillet lap joints as a minimum. For other bottoms, all welds shall be butt welds.

NC-4247.2 Bottom-to-Sidewall.

All welds shall meet the design requirements of NC-3933. Flat bottoms shall be attached to sidewalls by full penetration welds and fillet welds on each side as a minimum.

NC-4247.3 Roof-to-Sidewall.

Roof-to-sidewall joints shall be in accordance with the design requirements of NC-3933. The joints shall have continuous full fillet welds as a minimum.

NC-4247.4 Roofs.

Roofs shall be in accordance with the design requirements of NC-3933 and shall meet the requirements of NC-4241.

NC-4247.5 Nozzles.

Nozzle welds shall meet the requirements of NC-4244.

NC-4247.6 Special Requirements.

Special weld requirements for storage tanks are given in (a) through (d) below.

(a) The minimum size of fillet welds shall be as follows: plates $\frac{3}{16}$ in. (4.8 mm) thick, full fillet welds; plates over $\frac{3}{16}$ in. (4.8 mm) thick, not less than one-third the thickness of the thinner plate at the joint, with a minimum of $\frac{3}{16}$ in. (4.8 mm).

(b) Lap welded joints, as tack welded, shall be lapped not less than five times the nominal thickness of the thinner plate joined; but in the case of double welded lap joints the lap need not exceed 2 in. (51 mm), and in the case of single welded lap joints the lap need not exceed 1 in. (25 mm).

Page 247

FIG. NC-4244(e)-2 SOME ACCEPTABLE TYPES OF SMALL FITTINGS
For Definitions of Nomenclature, See NC-3352.4(e)

FIG. NC-4244(e)-2 SOME ACCEPTABLE TYPES OF SMALL FITTINGS

(c) For plates over $\frac{1}{2}$ in. (13 mm) thick in the sidewalls, roof, or bottom of the tank, if the thickness of two adjacent plates which are to be butt welded together differs more than $\frac{1}{8}$ in. (3.2 mm), the thicker plate shall be trimmed to a smooth taper extending for a distance at least three times the offset between the abutting surfaces so that the adjoining edges will be approximately the same thickness (Fig. NC-3361-1). The length of the required taper may include the width of the weld.

(d) The size of any weld along either edge of a compression ring shall not be less than the thickness of the thinner of the two parts joined or $\frac{1}{4}$ in. (6 mm), whichever is less, nor shall the size of the corner welds between the shell and a girder bar, such as shown in Fig. NC-3933.5(d)-1 sketches (d) and (e), or between the horizontal and vertical members of a compression ring assembly, such as shown in sketches (f) and (i), be less than the applicable value specified in Table NC-4247.6(d)-1.

NC-4247.7 Other Weld Joints.

The fabrication requirements for weld joints not specifically covered by NC-4247, such as sidewall weld joints and nozzle-to-flange weld joints, are the same as given in NC-4240 for Category A, B, and C weld joints for vessels.

NC-4250 WELDING END TRANSITIONS - MAXIMUM ENVELOPE

The welding ends of items or fittings shall provide a gradual change in thickness from the item or fitting to the adjoining item. Any welding end transition which lies entirely within the envelope shown in Fig. NC-4250-1 is acceptable, provided that:

- (a) the wall thickness in the transition region is not less than the min. wall thickness of the adjoining pipe; and
- (b) sharp reentrant angles and abrupt changes in slope in the transition region are avoided. When the included angle between any two adjoining surfaces of a taper transition is less than 150 deg., the intersection or corner (except for the weld

reinforcement) shall be provided with a radius of at least $0.05r_{min}$.

NC-4260 SPECIAL REQUIREMENTS FOR WELD JOINTS IN VESSELS DESIGNED TO NC-3200

NC-4261 General

Except for NC-4240, all other requirements of NC-4000 apply. The requirements of NC-4260 are to be used instead of those in NC-4240.

Page 251

NOTES:

- (1) Slip-on welding and welding-neck flanges shall conform to the requirements for 150-lb forged carbon steel raised-face flanges as given in ANSI B16.5.
- (2) Plate-ring flanges shall conform to all dimensional requirements for slip-on welding flanges, except that the extended hub on the back of the flange may be omitted.

FIG. NC-4246.5-3 SCREWED OR SOCKET WELD ROOF NOZZLES

FIG. NC-4246.5-3 SCREWED OR SOCKET WELD ROOF NOZZLES

NC-4262 Description and Limitations of Joint Types

The description of the joint types are as follows.

(a) *Type No. 1 Butt Joints.* Type No. 1 butt joints are those produced by double welding or by other means which produce the same quality of deposited weld metal on both inside and outside weld surfaces. Welds using backing strips which remain in place do not qualify as Type No. 1 butt joints. Type No. 1 butt joints shall have complete joint penetration and full fusion and shall meet the requirements of NC-4424 and NC-4426.

(b) *Type No. 2 Butt Joints.* Type No. 2 butt joints are single welded butt joints having backing strips which remain in place. NC-3252.2 gives stress concentration factors to be applied to Type No. 2 joints when a fatigue analysis is required. When Type No. 2 butt joints are used, care shall be taken on aligning and separating the components to be joined so that there will be complete penetration and fusion at the bottom of the joints for their full length. However, weld reinforcement need be supplied only on the side opposite the backing strip. The requirements of NC-4424 and NC-4426 shall be met.

(c) *Full Penetration Corner Joints.* Corner joints are those connecting two members approximately at right angles to each other in the form of an *L* or *T* and shall be made with full penetration welds.

(d) *Fillet Welded Joints.* Fillet welded joints, permitted by the rules of this subarticle, are those of approximately triangular cross section, joining two surfaces at approximately right angles to each other and having a

Page 252

throat dimension at least 70% of the smaller thickness of the parts being joined but not less than $\frac{1}{4}$ in. (6 mm).

FIG. NC-4246.5-4 WELDED BOTTOM OUTLET ELBOW

FIG. NC-4246.5-4 WELDED BOTTOM OUTLET ELBOW

**TABLE NC-4247.6(d)-1
MINIMUM SIZE FOR FILLET WELDS**

Thickness of the Thicker of the Two Parts Joined, in.	Minimum Size of Fillet Weld, in.
Not over $\frac{1}{4}$	$\frac{3}{16}$
Over $\frac{1}{4}$ through $\frac{3}{4}$	$\frac{1}{4}$
Over $\frac{3}{4}$ through $1\frac{1}{4}$	$\frac{5}{16}$
Over $1\frac{1}{4}$	$\frac{3}{8}$

TABLE NC-4247.6(d)-1 MINIMUM SIZE FOR FILLET WELDS

NC-4263 Category A Weld Joints

Category A weld joints shall be Type No. 1 butt joints.

NC-4264 Category B Weld Joints

Category B weld joints shall be Type No. 1 or Type No. 2 butt joints. Backing strips shall be removed from Type No. 2 joints unless access conditions prevent their removal. Backing strips shall be continuous, and any splices shall be butt welded. Circumferential single welded butt joints with one plate offset to form a backing strip are prohibited.

NC-4265 Category C Weld Joints

Category C weld joints shall be Type No. 1 butt joints or full penetration corner joints. Welds in full penetration corner joints shall be groove welds extending completely through at least one of the parts being joined and shall be fully fused to each part. Typical details are shown in Figs. NC-4265-1 and NC-4265-2.

⁴ One test specimen may represent a group of forgings, provided they are of the same nominal dimensions, from the same heat material and the same heat treatment lot, and forged in the same manner.

NC-4265.1 Flat Heads and Tubesheets With Hubs

(a) Hubs for butt welding to the adjacent shell, head, or other pressure parts, as shown in Fig. NC-4243.1-1 for flat heads, shall not be machined from flat plate. The hubs shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material in the direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen (subsize, if necessary) taken in this direction and as close to the hub as is practical.⁴ The minimum height of the hub shall be the lesser of $1\frac{1}{2}$ times the thickness of the

Page 253

pressure part to which it is welded or $\frac{3}{4}$ in. (19 mm), but need not be greater than 2 in. (51 mm).

GENERAL NOTES:

- Weld bevel is shown for illustration only.
- The weld reinforcement permitted by NC-4426 may lie outside the maximum envelope.

NOTES:

- The value of t_{min} is whichever of the following is applicable:
 - the minimum ordered wall thickness of the pipe;
 - 0.875 times the nominal wall thickness of pipe ordered to a pipe schedule wall thickness which has an under tolerance of 12.5%;
 - the minimum ordered wall thickness of the cylindrical welding end of a component or fitting (or the thinner of the two) when the joint is between two components.
- The maximum thickness at the end of the component is:
 - the greater of $t_{min} + 0.15$ in. or $1.15t_{min}$ when ordered on a minimum wall basis;
 - the greater of $t_{min} + 0.15$ in. or $1.0t_{nom}$ when ordered on a nominal wall basis.

FIG. NC-4265-1 ACCEPTABLE FULL PENETRATION DETAILS TO FORM A CORNER JOINT

FIG. NC-4265-2 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS

FIG. NC-4265-2 ACCEPTABLE FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS

(b) Hubbed flanges, as shown in Fig. XI-3120-1 sketches (6), (6a), and (6b), shall not be machined from flat plate.

NC-4266 Category D Weld Joints

Category D and similar weld joints shall be welded using one of the details of (a) through (d) below.

(a) *Butt Welded Attachments.* Nozzles shall be attached by Type No. 1 butt welds through either the vessel or the nozzle wall as shown in Fig. NC-4266(a)-1.

(b) *Full Penetration Corner Welded Attachment.* Nozzles shall be attached by full penetration welds through the wall of the vessel or nozzle as shown in Fig. NC-4266(b)-1. The welds shall be groove welds extending completely through at least one of the parts being joined and shall be fully fused to each part. Backing strips shall be used with welds deposited from only one side or when complete joint penetration cannot be verified by visual inspection. Backing strips, when used, shall be removed after welding.

(c) *Pad and Screwed Fitting Types of Welded Nozzles*

(1) *Inserted Nozzle Necks With Added Reinforcement.* Inserted type necks having added reinforcement in the form of one or more separate reinforcing plates shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle neck periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of the smaller of $0.7t_e$ or $0.7t$. The welds attaching the neck to the vessel wall and to the reinforcement shall be full penetration groove welds. Permissible types of weld attachments are shown in Fig. NC-4266(c)-1 sketches (a), (b), and (c).

(2) *Studded Connections*

(a) Studded connections, which may have externally imposed loads, shall have tapped holes complying with the requirements of NC-3262.4. The vessel or integral weld buildup shall have a flat surface machined on the shell to receive the connection. Drilled holes to be tapped shall not penetrate within one-fourth of the wall thickness from the inside surface of the vessel after deducting corrosion allowance unless at least the minimum thickness required as above is maintained by adding metal to the inside surface of the vessel.

(b) Studded pad-type connections may be used for connections on which there are essentially no external mechanical loads, such as manways and handholes used only as inspection openings or thermowell connections, provided the requirements of NC-3239.8 are met. The pad shall be attached by a fillet weld along the outer edge and a single bevel weld along the inner edge. Permissible type of weld attachment is shown in Fig. NC-4266(c)-1 sketch (d). The tapped

holes for stud threads shall comply with NC-3262.4.

(3) *Fittings With Internal Threads.* Internally threaded fittings shall be limited to 2 in. nominal pipe size (DN 50). They shall be attached by means of full penetration groove welds as illustrated in Fig. NC-4266(c)-1 sketches (e), (f), and (g), except pad type fittings, such as shown in sketch (h), which may be used if attached by means of fillet welds having a minimum throat dimension of the smaller of $0.7t_e$ or $0.7t$, as shown in sketch (h).

(d) *Attachment of Nozzles Using Partial Penetration Welds.* Partial penetration welds are limited by the restrictions of NC-3252.4(d). The weld size shall be

Page 256

such that the depth of penetration t_w will be at least $1/4 t_n$. Typical details are shown in Fig. NC-4266(d)-1.

FIG. NC-4266(a)-1 NOZZLES ATTACHED BY FULL PENETRATION BUTT WELDS

NC-4267 Types of Attachment Welds

Lugs, brackets, stiffeners, and other attachments shall be attached to the pressure retaining parts by continuous welds. Fillet or partial penetration welds shall be continuous on all sides.

NC-4300 WELDING QUALIFICATIONS

NC-4310 GENERAL REQUIREMENTS

NC-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure qualification requirements of Section IX and this Subsection may be used for welding pressure retaining material or attachments thereto. Any process used shall be such that the records required by NC-4320 can be prepared, except that records for stud welds shall be

Page 257

traceable to the welders and welding operators and not necessarily to each specific weld.

Sections Perpendicular and Parallel to the Cylindrical Vessel Axis

FIG. NC-4266(b)-1 FULL PENETRATION CORNER WELDED ATTACHMENTS

FIG. NC-4266(b)-1 FULL PENETRATION CORNER WELDED ATTACHMENTS

FIG. NC-4266(c)-1 PAD AND SCREWED FITTING TYPES OF WELDED NOZZLES AND OTHER CONNECTIONS TO SHELLS, DRUMS, AND HEADERS

FIG. NC-4266(c)-1 PAD AND SCREWED FITTING TYPES OF WELDED NOZZLES AND OTHER CONNECTIONS

TO SHELLS, DRUMS, AND HEADERS

FIG. NC-4266(d)-1 PARTIAL PENETRATION WELD CONNECTIONS

FIG. NC-4266(d)-1 PARTIAL PENETRATION WELD CONNECTIONS

NC-4311.1 Stud Welding Restrictions.

Stud welding is acceptable only for nonstructural and temporary attachments (NC-4435). Studs shall be limited to 1 in. (25 mm) maximum diameter for round studs and an equivalent cross-sectional area for studs of other shapes when welding in the flat position and $3/4$ in. (19 mm) diameter for all other welding positions. Postweld heat treatment shall comply with NC-4600, except that time at temperature need not exceed $1/2$ hr regardless of base material thickness. Welding procedure and performance qualification shall comply with the requirements of Section IX.

NC-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided:

- (a) temporary attachments are removed in accordance with the provisions of NC-4435(b);
- (b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec and the minimum thickness of the material to which the attachment is made is greater than 0.09 in. (2.3 mm); and
- (c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

NC-4311.4 Inertia and Continuous Drive Friction Welding

- (a) Inertia and continuous drive friction welding shall not be used for the fabrication of piping.
- (b) The weld between the two members shall be a full penetration weld.

NC-4320 WELDING QUALIFICATIONS, RECORDS, AND IDENTIFYING STAMPS

NC-4321 Required Qualifications

- (a) Each Certificate Holder is responsible for the welding done by his organization, and he shall establish the procedure and conduct the tests required by this

Page 260

Article and by Section IX in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures.

- (b) Procedures, welders, and welding operators used to join permanent or temporary attachments to pressure parts and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.

- (c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.

NC-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of his qualified welding procedures and of the welders and welding operators qualified by him, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

NC-4322.1 Identification of Joints by Welder or Welding Operator

- (a) Each welder or welding operator shall apply the identification mark assigned to him by the Certificate Holder on or adjacent to all permanent welded joints or series of joints on which he welds. The marking shall be at intervals of 3 ft (0.9 m) or less and shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in each item and of the welders and welding operators used in making each of the joints.

- (b) When a multiple number of permanent structural attachment welds, nonstructural welds, fillet welds, socket welds, welds of specially designed seals, weld

Page 262

metal cladding, hard surfacing and tube-to-tubesheet welds are made on an item, the Certificate Holder need not
identify the welder or welding operator who welded each individual joint, provided: Pages 261-261

FIG. NC-4267-1 ATTACHMENTS

FIG. NC-4267-1 ATTACHMENTS

$a \geq t/4; b \geq t/2; c \geq t$
 t = thickness of attached member
 c = minimum thickness of weld metal from the root to the face of the weld

GENERAL NOTE: All welds continuous.

FIG. NC-4267-1 ATTACHMENTS (CONT'D)

FIG. NC-4267-1 ATTACHMENTS (CONT'D)

- (1) the Certificate Holder maintains a system that will identify the welders or welding operators who made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;
- (2) the welds in each category are all of the same type and configuration and are welded with the same Welding Procedure Specification.
- (c) The identification of welder or welding operator is not required for tack welds.

NC-4323 Welding Prior to Qualifications

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with NC-4320 and Section IX shall be used.

NC-4324 Transferring Qualifications

The welding procedure qualifications and performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures, and shall not qualify welders or welding operators to weld for any other Certificate Holder, except as provided in Section IX, QW-201 and QW-300.20.

NC-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

NC-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented or modified by the requirements of this Article.

NC-4333 Heat Treatment of Qualification Welds for Ferritic Materials

Postweld heat treatment of procedure qualification welds shall conform to the applicable requirements of NC-4600 and Section IX. The postweld heat treatment time at temperature is to be at least 80% of the maximum time to be applied to the component weld material. The postweld heat treatment total time may be applied in one heating cycle.

NC-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test specimens. When each process cannot be included in the full size impact test specimen at the $\frac{1}{4}t$ location required by this Section, additional full size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full size test specimens. As an alternative, additional test welds can be made with each process so that full size specimens can be tested for each process.

NC-4334.1 Coupons Representing the Weld Deposits.

Impact test specimens and testing methods shall conform to NC-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $\frac{1}{4}t$ and, where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in NC-4620, and the test assembly is cooled at an accelerated rate, the longitudinal axis of the specimen shall be a minimum of t from the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld. Where drop weight specimens are required, the tension surface of the specimen shall be oriented parallel to the surface of the test assembly.

NC-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by NC-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be oriented either parallel to or perpendicular to the principal direction of rolling or forging.

Page 263

(b) The heat affected zone impact test specimens and testing methods shall conform to the requirements of NC-2321.2. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V-notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may be inclined to allow the root of the notch to align parallel to the fusion line. When a grain refining heat treatment is not performed on welds made by the electroslag or electrogas welding process, the notch for the impact specimens shall be located in the grain coarsened region.

(c) For the comparison of heat affected zone values with base material values [NC-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material. When required by NC-4335.2(b)(4), drop weight specimens shall be removed from a depth as near as practical to midway between the surface and center thickness of the unaffected base material and shall be tested in accordance with the requirements of NC-2321.1.

NC-4335 Impact Test Requirements

When materials are required to be impact tested per NC-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. Exemption from impact testing under NC-2311(a)(8) does not apply to weld metal unless the specific weld metal used is included in Table NC-2311(a)-1. Exemption from impact testing of the heat affected zone of those base materials exempted by NC-2311(a)(8) is not permitted. The weld procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of NC-2330 and NC-4334. Retests in accordance with the provisions of NC-2350 are permitted.

NC-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. in thickness when the weld will be made on the surface or will penetrate the base material that requires impact testing in accordance with NC-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with NC-2310, regardless of the depth of the repair. Exemption from impact testing under NC-2311(a)(8) does not apply to weld metal of welding procedure qualification tests for either production weld joints or base material repairs unless the specific weld metal used is included in Table NC-2311(a)-1.

(b) The impact test requirements and acceptance standards for welding procedure qualification weld metal shall be the same as specified in NC-2330 for the base material to be welded or repaired. Where two materials are to be joined by welding and have different fracture toughness requirements, the test requirements and acceptance standards of either material may be used for the weld metal, except where otherwise specified by NCA-1280 or other parts of this Section.

(c) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB or NE may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection.

NC-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. (16 mm) and either of the base materials require impact testing in

accordance with the rules of NC-2310. Exemption of base materials by NC-2311(a)(8) does not apply to the welding procedure qualification heat affected zone or unaffected base material for such materials. The only exceptions to the requirements are the following:

(1) the qualification for welds in P-Nos. 1 and 3 and SA-336 F12 materials that are postweld heat treated and are made by any process other than electroslog, electrogas, or thermit;

(2) the qualification for weld deposit cladding or hear-facing on any base material.

(b) Impact testing of the procedure qualification test heat affected zone, where required by NC-4335, shall be conducted in accordance with (b)(1) through (3) below, or (b)(4) through (6) below, and (c) below, as applicable.

(1) For tests of welding procedure qualifications for materials that require testing in accordance with NC-2332.1, the three Charpy V-notch heat affected zone specimens and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with NC-2331(a)(1). The Charpy V-notch impact test of the unaffected

Page 264

base material shall meet the requirements of Table NC-2332.1-1 or Table NC-2332.1-2. If the average lateral expansion value of the three heat affected zone specimens is equal to or greater than the average value of the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable, and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(2) If the heat affected zone Charpy V-notch average toughness value of (b)(1) above is less than the unaffected base material value, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data shall then be obtained, as specified in (b)(3) below, to provide an additive temperature for the adjustment of the lowest service temperature (LST) of the base material that is to be welded in production with the welding procedure that is being qualified. Alternatively, the welding procedure qualification may be rewelded and retested.

(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification test heat affected zone or the unaffected base material, or both, at temperatures which provide toughness values that meet or exceed those required for the thickness or thickness-strength combination of the material to be welded in production. The average toughness data for the heat affected zone and unaffected base material shall be plotted on a property-temperature chart. The temperature at which these two sets of data exhibit a common acceptable value of toughness for the production thickness or thickness-strength combination involved shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(2) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the highest LST established by the tests of NC-2332.1 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NC-2332.1 will still apply as stated in (b)(1) above. Where the actual LST is not required for the production material to be welded, for example, where a testing temperature is established by the Design Specification to determine that the material has adequate toughness to meet the requirements at the specified test temperature, the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(4) For tests of welding procedure qualifications for materials that require tests in accordance with NC-2332.2, three Charpy V-notch heat affected zone specimens and three Charpy V-notch unaffected base material specimens shall be tested at a temperature lower than or equal to the LST. The Charpy V-notch impact tests of the unaffected base material shall each meet or exceed the applicable Over $2\frac{1}{2}$ in. (64 mm) thickness requirements of Table NC-2332.1-1 or Table NC-2332.1-2. If the average toughness value of the three heat affected zone specimens is equal to or greater than the average value for the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable. The values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(5) If the average Charpy V-notch toughness value for the heat affected zone of (b)(4) above is less than that for the unaffected base material, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test

results may be recorded on the Welding Procedure Qualification Record. Data of (b)(6) below, which will provide an adjustment temperature for any base material for which the welding procedure is being qualified, shall be included. Alternatively, the welding procedure qualification may be rewelded and retested.

(6) The data for use in (b)(5) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification heat affected zone or the unaffected base material, or both, at temperatures which provide toughness values equal to or greater than the applicable Over $2\frac{1}{2}$ in. (64 mm) thickness requirements of Table NC-2332.1-1 or Table NC-2332.1-2. The average toughness data for the heat affected zone and the unaffected base material shall be plotted on a property-temperature chart. The temperatures at which these two sets of data exhibit a common toughness value equal to or greater than the applicable Over $2\frac{1}{2}$ in. thickness requirements of Table NC-2332.1-1 or Table NC-2332.1-2 shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(5) above as the adjustment temperature. The adjustment

Page 265

temperature shall be added to the highest T_{NDT} established by the tests of NC-2332.2 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or is a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NC-2332.2 will still apply as stated in (b)(4) above. Where the actual T_{NDT} is not required for the product material to be welded, for example, where a testing temperature is established by the Design Specification to determine that the T_{NDT} is at or below the specified temperature, the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) or (b)(4) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact tests of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average toughness of the heat affected zone relative to the average toughness of the unaffected base material shall be followed as in (b)(1) through (3) above or (b)(4) through (6) above, as applicable, to determine the data which are to be recorded on the Welding Procedure Qualification Record.

(d) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB or NE may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection.

NC-4336 Qualification Requirements for Built- Up Weld Deposits

Built-up weld deposits for base metal reinforcement shall be qualified in accordance with the requirements of NC-4331 to NC-4335, inclusive.

NC-4350 SPECIAL QUALIFICATION REQUIREMENTS FOR TUBE-TO-TUBESHEET WELDS

NC-4351 General Requirements

The welding procedure for tube-to-tubesheet welds shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed below are made in the procedure. Changes other than those given may be made in a procedure without the necessity for requalification, provided the procedure specification is amended to show these changes.

NC-4352 Essential Variables for All Welding Processes

Essential variables for all welding processes shall be as listed in (a) through (k) below:

(a) a Change from one welding process to any other welding process or combination of welding processes;

(b) a change in the P-Number classification of tube material in Section IX, QW-422. A separate qualification is required for each tube material which is not included under any P-Number;

(c) a change in the P-Number of the tube sheet base material. The base material may be a homogeneous material or a cladding material of wrought type or weld-overlay type. If welding is performed between the tube and cladding, the cladding shall be considered the base material. A separate qualification is required for welding tubes to base material or cladding material which is not included under any P-Number;

(d) a change in the weld metal analysis of the deposited weld metal as given in (1) and (2) below:

(1) a change from any A-Number in QW-442 of Section IX to any other A-Number or to any F-Number in QW-432 or to any analysis not listed in the tables, except that each AISI type similar to A-No. 7 or A-No. 8 of QW-442, shall require separate qualifications;

(2) a change from any F-Number in QW-432 to any other F-Number or to any A-Number in QW-442 or to any analysis not listed in the tables;

(e) for tubes of specified wall thicknesses of 0.100 in. or less, an increase or decrease of 10% of specified wall thickness or specified diameter;

(f) for specified wall thicknesses greater than 0.100 in., only one qualification test is required;

(g) a decrease of 10% or more in the specified width of the ligament between tube holes when the specified width of the ligament is less than the greater of $\frac{3}{8}$ in. (10 mm) or three times the specified tube wall thickness;

(h) the addition of other welding positions than those already qualified (Section IX, QW-461.1).

(i) a change in the specified preheating temperature range;

(j) a change in the specified postweld heat treating temperature;

(k) a change from multiple pass to single pass or vice versa.

Page 266

NC-4353 Essential Variables for Shielded Metal-Arc Welding

An additional essential variable for shielded metal-arc welding is an increase in electrode diameter.

NC-4354 Essential Variables for Gas Tungsten- Arc and Gas Metal-Arc Welding

Additional essential variables for gas tungsten-arc and gas metal-arc welding are as given in (a) through (f) below:

(a) a change in the configuration of the tubesheet at the tube hole edges, including the addition or omission of preplaced metal inserts;

(b) a change in the size or shape of preplaced metal inserts;

(c) a change from one shielding gas to another shielding gas or to a mixture of shielding gases;

(d) when using mixed shielding gas, a change of plus or minus 25% or 5 cu ft/hr (0.14 m³/hr), whichever is the larger, in the rate of flow of the minor gas constituent;

(e) for gas tungsten-arc welding process, the addition or omission of filler metal;

(f) a change in the nominal diameter of the filler metal.

NC-4355 Essential Variables for Explosive Welding

Additional essential variables for explosive welding are as given in (a) through (e) below:

(a) an increase or decrease in the specified tube wall thickness or diameter of 10% for all diameters and wall thicknesses instead of the provision of NC-4352(e);

(b) a change in the method of pressure application;

(c) a change in the type of explosive or a change in energy content of plus or minus 10%;

- (d) a change of plus or minus 10% in the placement of the charge from the tube sheet face;
- (e) a change in the specified clearance between the tube and the tube sheet of plus or minus 10%.

NC-4356 Test Assembly

The procedure qualification shall be made on a test assembly which simulates the conditions to be used in production with respect to the tube hole pattern and the essential variables listed in NC-4352 through NC-4354. In addition, the thickness of the tubesheet in the test assembly shall be as thick as the production tubesheet, except it need not exceed 2 in. (51 mm). The minimum required number of weld joints shall be ten.

NC-4357 Examination of Test Assembly

The assembly shall be examined by a liquid penetrant method in accordance with the requirements of NC-5110 and shall meet the acceptance standards of NC-5350. Following this, the assembly shall be sectioned longitudinally through each tube. The thickness of the assembly may be reduced to $\frac{1}{2}$ in. (13 mm) prior to this sectioning. The four faces of each tube exposed by sectioning shall be polished and etched with a suitable etchant and shall be visually examined for cracks. The weld throat, minimum leakage path, shall be not less than two-thirds of the specified tube wall thickness, and the weld shall be free from cracks on visual examination with $\times 10$ magnification.

NC-4358 Performance Qualification

NC-4358.1 Welders.

The requirements for the performance qualification test for welders shall be the same as those for the procedure qualification, except that the minimum required number of tubes in the test assembly shall be six.

NC-4358.2 Welding Operators.

The requirements for the performance qualification test for welding operators (automatic weld process) shall be the same as those for the procedure qualification, except that:

- (a) the essential variables for performance qualification are those detailed in NC-4352(a), (b), (c), (d), and (h), and
- (b) the minimum required number of tubes in the test assembly shall be six.

NC-4360 QUALIFICATION REQUIREMENTS FOR WELDING SPECIALLY DESIGNED WELDED SEALS

NC-4361 General Requirements

(a) Specially designed welded seals are defined as the walls or membranes, such as an omega shaped seal membrane, which confine the fluid and where strength is provided by a separate device.

(b) The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the essential variables specified or listed in the following paragraphs are made in the procedure. Changes other than those given may be made in the procedure without the necessity for requalification,

Page 267

provided the procedure is amended to show these changes. In addition, the essential variables specified in Section IX shall apply for both procedure and performance qualification.

NC-4362 Essential Variables for Automatic, Machine, and Semiautomatic Welding

The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed in this paragraph or the applicable portions of Section IX are made:

- (a) when preplaced filler metal is melted to form all or part of a weld, a change from one alloy type or classification to

any other alloy type or classification of base material or filler metal, even though previously qualified base materials and filler metals are of the same P-Number or A-Number;

(b) a change of any dimension of the weld joint for automatic welding or a change of any dimension of the weld joint by more than 10% for semiautomatic or machine welding beyond that qualified;

(c) a change in the nominal size or shape of any filler metal added to the arc;

(d) for automatic welding, an increase or decrease in the length of the seal weld by more than 30%;

(e) for automatic welding, a change in the welding current greater than 50% of the difference between the maximum and minimum amperages used during qualification; only two test assemblies need to be welded for requalification;

(f) any change in the angular relationship or distance between the welding electrode and the work and the filler metal beyond the range qualified;

(g) the addition or deletion of the use of tack welds or locating fixtures to facilitate alignment or to maintain the root opening of the weld joint;

(h) the addition or deletion of consumable inserts.

NC-4363 Essential Variables for Manual Welding

The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed in (a) or (b) below are made in the procedure:

(a) a change of more than $\pm 10\%$ of any dimension, excluding angularity of the groove, of the weld joint cross section, except that base material thickness may vary from the minus 10% to 2.5 times the thickness qualified when welding parts of the same material thickness or the thin member may vary from minus 10% to two times the thickness qualified when welding a thin seal membrane to a thick member;

(b) when preplaced filler metal is melted to form all or a part of a weld, a change from one type or classification to any other type or classification of base material or filler metal, even though previously qualified base materials and filler metals are of the same P-Number or A-Number.

NC-4366 Test Assembly

The test assembly shall consist of a duplicate of the production weld, except that tolerances as stated in NC-4362(b) or NC-4363(a) are permitted. Except for automatic welding, the Certificate Holder may use a 12 in. length to qualify, if the length of the production weld is considered to be greater than necessary to qualify.

NC-4366.1 Automatic Welding.

For automatic welding, at least six consecutive test assemblies representing the range of dimensions to be qualified shall be required to establish the reproducibility of the welding procedure. In addition, the Certificate Holder making the production welds shall verify this capability of making two consecutive test assemblies prior to production welding using the previously qualified procedure.

NC-4366.2 Manual, Machine, and Semiautomatic Welding.

For manual, machine, and semiautomatic welding, two test assemblies shall be required.

NC-4367 Examination of Test Assembly

(a) Where 100% weld penetration is required, the test assembly shall be sectioned, if necessary, to permit examination of the entire underside weld surface.

(b) A minimum of four cross sections shall be taken from each test assembly and examined. One cross section shall be made in a weld start-and-stop area and the others shall be taken at random. When doubt exists as to the acceptability of the weld after examination of four cross sections, the Inspector may require that additional metallographic cross sections be prepared for examination of the weld and adjacent base material. All cross sections shall be examined in accordance with

NC-5370.

NC-4368 Performance Qualification Test

The performance qualification test assembly shall meet the same requirements specified for the procedure qualification test assembly in NC-4366 and shall be examined in accordance with NC-4367. Furthermore,

Page 268

welding operators shall qualify using the welding machine which will be used to make production welds and shall be required to set up the machine with regard to adjustments and settings which affect the welding characteristics. One test assembly is required.

NC-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

NC-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

NC-4411 Identification, Storage, and Handling of Welding Materials

Each Certificate Holder is responsible for control of the welding electrodes and other materials which are used in the fabrication and installation of components (NC-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding materials shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

NC-4412 Cleanliness and Protection of Welding Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

NC-4420 RULES FOR MAKING WELDED JOINTS

NC-4421 Backing Rings

Backing rings which remain in place may be used for piping in accordance with the requirements of NC-3661.2. The materials for backing rings shall be compatible with the base metal, but spacer pins shall not be incorporated into the weld.

NC-4422 Backup Plates, Backing Rings, and Compression Rings or Stiffeners for Storage Tanks

Backup plates and backing rings which remain in place and compression rings or stiffeners of storage tanks, such as angles, bars, and ring girders, may be used. The materials used for such backup plates, backing rings, and compression rings or stiffeners shall be compatible with the base metal, but spacer pins shall not be incorporated into the weld.

NC-4423 Double Welded Joints, Single Welded Joints, and Peening

NC-4423.1 Double Welded Joints.

Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetrations are otherwise obtained and demonstrated to be satisfactory by welding procedure qualifications.

NC-4423.2 Single Welded Joints.

Where single welded joints are used, particular care shall be taken in aligning and separating the components to be joined so that there will be complete penetration and fusion at the bottom of the joint for its full length.

NC-4423.3 Peening.

Controlled peening may be performed to minimize distortion. Peening shall not be used on the internal layer (root) of the weld metal nor on the final layers unless the weld is postweld heat treated.

NC-4424 Surfaces of Welds

As-welded surfaces are permitted except for inertia and continuous drive friction welding where the flash shall be removed to sound metal. For piping, the appropriate stress indices given in Table NB-3683.2-1 shall be applied. However, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys to meet the requirements of (a) through (e) below.

(a) The surface condition of the finished weld shall be suitable for the proper interpretation of radiographic and other required nondestructive examination of the weld. In those cases where there is a question regarding the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Reinforcements are permitted in accordance with NC-4426.1 for vessels, pumps, and valves, and NC-4426.2 for piping.

(c) Undercuts shall not exceed $\frac{1}{32}$ in. (0.8 mm) and shall not encroach on the required section thickness.

(d) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting

Page 269

thickness of the weld meets the requirements of NC-3000.

(e) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the required thickness.

(f) For inertia and continuous drive friction welding, the weld upset shall meet the specified amount within $\pm 10\%$.

NC-4425 Welding Components of Different Diameters

When components of different diameters are welded together, there shall be a gradual transition between the two surfaces. The slope of the transition shall be such that the length-offset ratio shall not be less than 3:1 (Figs. NC-3361-1 and NC-4233-1), unless greater slopes are shown to be acceptable by analysis for vessels designed to NC-3200. The length of the transition may include the weld.

NC-4426 Reinforcement of Welds

NC-4426.1 Thickness of Weld Reinforcement for Vessels, Pumps, and Valves.

The surface of the reinforcement of all butt welded joints in vessels, pumps, and valves may be flush with the base material or may have uniform crowns. The height of reinforcement on each face of the weld shall not exceed the thicknesses in the following tabulation:

Nominal Thickness, in.	Maximum Reinforcement, in.
Up to 1, incl.	$\frac{3}{32}$
Over 1 to 2, incl.	$\frac{1}{8}$
Over 2 to 3, incl.	$\frac{5}{32}$
Over 3 to 4, incl.	$\frac{7}{32}$
Over 4 to 5, incl.	$\frac{1}{4}$
Over 5	$\frac{5}{16}$

NC-4426.2 Thickness of Weld Reinforcement for Piping.

For double welded butt joints, the limitation on the reinforcement given in Column 1 of the following tabulation shall apply separately to both inside and outside surfaces of the joint. For single welded butt joints, the reinforcement given in Column 2 shall apply to the inside surface and the reinforcement given in Column 1 shall apply to the outside surface. The reinforcements shall be determined from the higher of the abutting surfaces involved.

Material Nominal Thickness, in.	Maximum Reinforcement Thickness, in.	
	Column 1	Column 2
Up to $\frac{1}{8}$ incl.	$\frac{3}{32}$	$\frac{3}{32}$
Over $\frac{1}{8}$ to $\frac{3}{16}$ incl.	$\frac{1}{8}$	$\frac{3}{32}$
Over $\frac{3}{16}$ to $\frac{1}{2}$ incl.	$\frac{5}{32}$	$\frac{1}{8}$
Over $\frac{1}{2}$ to 1, incl.	$\frac{3}{16}$	$\frac{5}{32}$
Over 1 to 2, incl.	$\frac{1}{4}$	$\frac{5}{32}$
Over 2	The greater of $\frac{1}{4}$ in. or $\frac{1}{8}$ times width the weld inches.	$\frac{5}{32}$

NC-4427 Shape and Size of Fillet Welds

(a) Fillet welds may vary from convex to concave. Except as permitted in (b) below, the shape and size of the weld shall be in accordance with the requirements of Fig. NC-4427-1. A fillet weld in any single continuous weld may be less than the specified fillet weld dimension by not more than $\frac{1}{16}$ in. (1.6 mm), provided that the total undersize portion of the weld does not exceed 10% of the length of the weld. Individual undersize weld portions shall not exceed 2 in. (51 mm) in length. In making socket welds, a gap as shown in Fig. NC-4427-1 shall be provided prior to welding. The gap need not be present nor be verified after welding. For sleeve type joints without internal shoulder, the gap shall be between the butting ends of the pipe or tube.

(b) Socket welds smaller than those specified in Fig. NC-4427-1 may be used provided the requirements of NC-3000 are met.

NC-4428 Seal Welds of Threaded Joints

Where seal welding of threaded pipe joints is performed, the exposed threads shall be either removed entirely or covered with weld metal.

NC-4430 WELDING OF ATTACHMENTS

NC-4431 Materials for Attachments

Nonpressure-retaining attachments (NC-1132.1) welded to pressure retaining components shall be of materials which meet the requirements of NC-2190. Materials for pressure retaining attachments shall meet the requirements of NC-2120.

Page 270

Page 271

GENERAL NOTE:

The size of an equal leg fillet weld is the leg length of the largest inscribed right isosceles triangle.
Theoretical throat = $0.7 \times$ size of weld.

(a) Equal Leg Fillet Weld

GENERAL NOTE:

The size of an unequal leg fillet weld is the shorter leg length of the largest right triangle which can be inscribed within the fillet weld cross section.

(b) Unequal Leg Fillet Weld

Front and Back Weld

Face and Back Weld

(c-2) Socket Welding Flange

(c-3) Socket Welding Fittings

GENERAL NOTES:

$x \text{ min.} = 1.4t_n$ or thickness of the hub, whichever is smaller, but not less than $1/8 \text{ in.}$

$C_x \text{ min.} = 1.09t_n$ where $t_n =$ nominal pipe wall thickness

(c) Minimum Welding Dimensions for Slip-on and Socket Welding Flanges and Socket Welding Fittings

FIG. NC-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

FIG. NC-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

NC-4432 Welding of Structural Attachments

The rules of NC-4321 governing welding qualifications shall apply to the welding of structural attachments to pressure retaining material.

NC-4433 Structural Attachments

Structural attachments shall conform reasonably to the curvature of the surface to which they are to be attached and shall be attached by full penetration, fillet, or partial penetration continuous or intermittent welds. Figure NC-4433-1 illustrates some of the typical details for attaching structural attachments to a component using full penetration welds. Valve seats may be attached to the pressure boundary part by fillet or partial penetration welds, provided the valve seat is shouldered against the pressure boundary part.

NC-4434 Welding of Internal Structural Supports to Clad Components

Internal structural supports on clad components shall be welded to the base metal and not to the cladding except for weld overlay cladding.

NC-4435 Welding of Nonstructural and Temporary Attachments and Their Removal

(a) Nonstructural attachments (NC-1132.1) welded to the pressure retaining portion of the component need not comply with NC-2000 and may be welded with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (4) below are met.

- (1) The welding procedure and the welders have been qualified in accordance with NC-4321.
- (2) The material is identified and is compatible with the material to which it is attached.
- (3) The welding material is identified and is compatible with the materials joined.
- (4) The welds are postweld heat treated when required by NC-4620.

(b) Except for tanks or tank parts, removal of nonstructural attachments, when temporary, shall be accomplished as follows.

- (1) The immediate area around the temporary attachment is marked in a suitable manner so that after removal the area can be identified until after it has been examined in accordance with (3) below.
 - (2) The temporary attachment is completely removed in accordance with the procedures of NC-4211.
 - (3) After the temporary attachment has been removed, the marked area is examined by the liquid penetrant or magnetic particle method in accordance with the requirements of NC-5110 and meets the acceptance standards of NC-5340 or NC-5350, whichever is applicable.
 - (4) As an alternative to (a)(4) above, postweld heat treatment may be deferred until after removal of the attachment.
- (c) For tanks and tank parts, removal of temporary attachments shall be in accordance with (b)(2) and (b)(4) above.

NC-4436 Installation of Attachments to Piping Systems After Testing

Attachments may be welded to the piping system after performance of the pressure test provided that:

- (a) the welds do not require PWHT under NC-4622.7;
- (b) welds shall be restricted to fillet welds not exceeding $\frac{3}{8}$ in. (10 mm) throat thickness and to full penetration welds attaching materials not exceeding $\frac{1}{2}$ in. (13 mm) in thickness;
- (c) welds shall not exceed a total length of 24 in. (610 mm) for fillet welds or 12 in. (305 mm) for full penetration welds; and

(d) welds shall be examined as required by NC-5000.

NC-4437 Attachment of Stiffener Rings

NC-4437.1 General Requirements.

All permanent and temporary attachments of stiffener rings to shells, including tack welds, shall be made by qualified welders using qualified welding procedures.

NC-4437.2 Attachment of Stiffening Rings to Shell

(a) Stiffening rings, when used, may be placed on the inside or outside of a vessel and shall be attached to the shell by welding or bolting. The ring shall be in contact with the shell.

(b) Stiffening rings may be attached to the shell by either continuous or intermittent welding. The total length of the intermittent welding on each side of the stiffening ring shall be:

- (1) not less than one-half the outside circumference of the component for rings on the outside; and
- (2) not less than one-third the circumference of the vessel for rings on the inside.

Acceptable arrangements and spacings of intermittent welds are shown in Fig. NC-4437.2(b)-1. Welds on opposite sides of the stiffener may be either staggered or in-line as indicated.

Page 272

Page 273

GENERAL NOTE: The welds may be partial penetration or fillet welds.

FIG. NC-4433-1 TYPES OF ATTACHMENT WELDS

FIG. NC-4433-1 TYPES OF ATTACHMENT WELDS

FIG. NC-4437.2(b)-1 SOME ACCEPTABLE METHODS OF ATTACHING STIFFENING RINGS TO SHELLS OF CYLINDRICAL VESSELS SUBJECTED TO EXTERNAL PRESSURE

FIG. NC-4437.2(b)-1 SOME ACCEPTABLE METHODS OF ATTACHING STIFFENING RINGS TO SHELLS OF CYLINDRICAL VESSELS SUBJECTED TO EXTERNAL PRESSURE

(c) All welding of stiffening rings shall comply with the requirements of this Subsection. In areas where a corrosion allowance is specified in the Design Specification, stiffening rings shall be attached to the shell with a continuous fillet weld, seal weld, or full penetration weld.

NC-4450 REPAIR OF WELD METAL DEFECTS

NC-4451 General Requirements

Defects in weld metal detected by the examinations required by NC-5000 or by the tests of NC-6000 shall be eliminated and repaired when necessary or the indication reduced to an acceptable limit.

NC-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining and need not be repaired by welding, provided the requirements of (a), (b), and (c) below are met.

(a) The remaining thickness of the section is not reduced below that required by NC-3000.

(b) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(c) The area is examined by a magnetic particle or liquid penetrant method in accordance with NC-5110 after blending and meets the acceptance standards of NC-5300 to ensure that the defect has been removed or the indication reduced to an acceptable limit. Defects detected by visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

NC-4453 Requirements for Making Repairs of Welds

Excavations in weld metal, when repaired by welding, shall meet the requirements of the following subparagraphs.

NC-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with NC-5110 and meet the acceptance standards of NC-5340 or NC-5350. This examination is not required where defect elimination removes the full thickness of the weld and where the backside of the weld joint is not accessible for removal of examination materials.

NC-4453.2 Requirements for Welding Materials, Procedures, and Welders.

The weld repair shall be made using welding materials, welders, and welding procedures qualified in accordance with NC-4125 and NC-4300.

NC-4453.3 Blending of Repaired Areas.

After repair the surface shall be blended uniformly into the surrounding surface.

NC-4453.4 Examination of Repair Welds

(a) The examination of a weld repair shall be repeated as required for the original weld, except that it need only be reexamined by the liquid penetrant or magnetic particle method when the unacceptable indication was originally detected by the liquid penetrant or magnetic particle method and when the repair cavity does not exceed the following:

(1) $\frac{1}{3}t$ for $t \leq \frac{3}{4}$ in.

(2) $\frac{1}{4}$ in. for $\frac{3}{4}$ in. $\leq t \leq 2\frac{1}{2}$ in.

(3) the lesser of $\frac{1}{8}$ in. or $10\%t$ for $t > 2 \frac{1}{2}$ in.

where t equals the thickness of the weld.

Page 274

(b) When repairs to welds joining P-No. 1 and P-No. 3 materials require examination by radiography as required in (a) above, but construction assembly prevents meaningful radiographic examination, ultrasonic examination may be substituted, provided that:

(1) the weld has been previously radiographed and met the applicable acceptance standards;

(2) the ultrasonic examination is performed using a procedure in accordance with Section V, Article V to the acceptance standards of NC-5330;

(3) the substitution is limited to Category A and B welds in vessels and similar type welds in other items.

The absence of suitable radiographic equipment is not justification for the substitution.

NC-4453.5 Heat Treatment of Repaired Areas.

The area shall be heat treated in accordance with NC-4620.

NC-4500 BRAZING

NC-4510 RULES FOR BRAZING

NC-4511 Where Brazing May Be Used

(a) Brazing is permitted for the attachment of tubes to tubesheets and as permitted for pipe joints in NC-3671.6. Appurtenances and piping with outside diameter equal to that of NPS 1 (DN 25) and less for all other materials may be fabricated using brazed joints in accordance with Fig. NC-4511-1.

(b) Valves with inlet piping connections of NPS 4 (DN 100) and less may have seats brazed to the valve body or bonnet, provided the seat is shouldered against the pressure boundary part.

(c) Headers, NPS 4 (DN 100) and less, fabricated from copper, copper alloys, or copper-nickel alloys, which are an integral part of finned tubular heat exchangers, may utilize brazed joints fabricated in accordance with Fig. NC-4511-1.

NC-4512 Brazing Material

Where brazing is permitted, the brazing filler material and fluxes shall conform to the rules covering identification in NC-2150 and to the requirements of (a), (b), and (c) below.

(a) The filler material used in brazing shall be a nonferrous metal or alloy with a solidus temperature above 800°F (427°C) and at least 500°F (278°C) above the highest temperature of the joint in service.

(b) The filler material shall melt and flow freely by capillary action within the desired temperature range, and in conjunction with a suitable flux or controlled atmosphere the filler material shall wet and adhere to the surfaces to be joined.

(c) Fluxes that are fluid and chemically active at the brazing temperature shall be used, when necessary, to prevent oxidation of the filler metal and the surfaces to be joined, and to promote free flowing of the filler material.

NC-4520 BRAZING QUALIFICATION REQUIREMENTS

NC-4521 Brazing Procedure and Performance Qualifications

Qualification of the brazing procedure to be used and of the performance of brazers and brazing operators is required and shall comply with the requirements of Section IX, except that validation of the procedure qualification per QB-451.5 Note (1) is not required for the furnace brazing of seat rings to bodies or bonnets of valves having inlet piping connections of 4 in. nominal size (DN 100) and less. When the Design Temperature is greater than 200°F (93°C), tension testing shall be

in. nominal size (DN 100) and less. When the Design Temperature is greater than 200°F (93°C), tension testing shall be performed at the Design Temperature.

NC-4522 Brazing Requalification Requirements

In addition to the requirements of Section IX, the brazing procedure shall be set up as a new procedure specification and shall be completely requalified when the construction of the brazed components includes reheating of any portion of the completed brazed joint to a temperature that is within 300°F (167°C) of the solidus temperature of the filler metal.

NC-4530 FITTING AND ALIGNING OF PARTS TO BE BRAZED

Parts to be joined by brazing shall be fitted, and retained in position during the brazing operation within the tolerances specified in the brazing procedure specification. Brazed joints shall be assembled in a sequence which will permit the maximum number of joints to be visually examined on both sides of the joint after brazing.

Page 275

Page 276

- t = thickness of part penetrated
 t_n = nominal thickness of connecting part
 d = outside diameter of part B
 c = clearance or interference between mating parts and shall be in accordance with the brazing procedure specification
 z = depth of engagement and shall be the lesser of $3t_n$ or d , but in no case less than 1/4 in.

GENERAL NOTES:

- (1) Part A shall be attached to a component in accordance with the requirements for the component proper.
- (2) Part B shall be attached either to part A or to another part B by the joints shown above, or in accordance with the requirements of the component proper.
- (3) Grooves for preplaced filler metal are permitted, provided the reduction in cross section due to the grooves is considered in the design.

FIG. NC-4511-1 BRAZED CONNECTIONS FOR APPURTENANCES AND PIPING

NC-4540 EXAMINATION OF BRAZED JOINTS

The completed brazed joints shall be visually examined on all accessible surfaces in accordance with NC-5275.

NC-4600 HEAT TREATMENT

NC-4610 WELDING PREHEAT REQUIREMENTS

NC-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thicknesses. Some practices used for preheating are given in Appendix D as a general guide for the materials listed by P-Number of Section IX. It is cautioned that the preheating suggested in Appendix D does not necessarily ensure satisfactory completion of the welded joint and that the preheating requirements for individual materials within the P-Number listing may be more or less restrictive. The welding procedure specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

NC-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does not harm the base material or any weld metal already applied or which does not introduce deleterious material into the welding area which is harmful to the weld.

NC-4613 Interpass Temperature

Consideration must be given to the limitations of interpass temperatures for quenched and tempered materials to avoid detrimental effects on the mechanical properties.

NC-4620 POSTWELD HEAT TREATMENT

NC-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

NC-4622 PWHT Time and Temperature Requirements

NC-4622.1 General Requirements.⁵

Except as otherwise permitted in NC-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperature shall be maintained within the temperature ranges for the minimum holding time specified in Table NC-4622.1-1 except as otherwise permitted in NC-4622.4(c). P-Number groups in Table NC-4622.1-1 are in accordance with Section IX, QW-420. Except as provided in NC-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. In addition, the requirements of the following subparagraphs shall apply

NC-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Authorized Inspector. Identification on the time-temperature recording shall be to the weld, part, or component. A summary of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

NC-4622.3 Definition of Nominal Thickness Governing PWHT.

Nominal thickness in Table NC-4622.7(b)-1 is the thickness of the weld, the pressure retaining material for structural attachment welds or the thinner of the pressure retaining materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. For fillet welds the nominal thickness is the throat thickness, and for partial penetration and material repair welds the nominal thickness is the depth of the weld groove or preparation.

NC-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table NC-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat-treat cycles.

5 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

Page 277

Page 278

TABLE NC-4622.1-1
MANDATORY REQUIREMENTS FOR POSTWELD HEAT
TREATMENT OF WELDS¹

P-No. (Sect. IX, QW-420)	Holding Temperature Range [Note (2)]	Minimum Holding Time at Temperature for Weld Thickness (Nominal)			
		$\frac{1}{2}$ in. or less	Over $\frac{1}{2}$ in. to 2 in.	Over 2 in. to 5 in.	Over 5 in.
1, 3	1100–1250°F	30 min	1 hr/in.	2 hr plus 15 min each additional inch over 2 in.	2 hr plus 15 min each additional inch over 2 in.
4	1100–1250°F	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
5A, 5B, 5C, 6 (except P-No. 6 Gr. 4)	1250–1400°F	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
6 Gr. 4	1050–1150°F				
7	1300–1400°F	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
9A Gr. 1	1100–1250°F	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
9B Gr. 1	1100–1175°F				
10C Gr. 1, 10F Gr. 1	1100–1250°F	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
10I Gr. 1	1300–1400°F				
11A Gr. 4	1000–1050°F	30 min	1 hr/in.	1 hr/in.	1 hr/in.
P-Nos. 8, 10H Gr. 1, 34, 42, 43, 45 and hard sur- facing on P-No. 1 base metal whose reported carbon content is not more than 0.30%	PWHT neither required nor prohibited				

NOTES:

- (1) Exemptions to the mandatory requirements of this Table are defined in NC-4622.7.
(2) All temperatures are metal temperatures.

**TABLE NC-4622.4(c)-1
ALTERNATIVE HOLDING TEMPERATURES
AND TIMES¹**

Material P-Numbers	Alternative Minimum Holding Temperatures, °F	Alternative Minimum Holding Times
1, 3, 9A Gr.1 9B Gr.1	1050	2 hr/in. thick
1, 3, 9A Gr.1, 9B Gr.1	1000	4 hr/in. thick

NOTE:

(1) All other requirements of NC-4622 shall apply.

TABLE NC-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

(b) Holding time at temperature in excess of the minimum requirements of Table NC-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with NC-2200, NC-2400, and NC-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table NC-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table NC-4622.4(c)-1 and (1), (2), and (3) below.

(1) Except for P-No. 1 materials, when welds in the materials listed in Table NC-4622.4(c)-1 are to be postweld heat treated at the lower minimum temperatures, the impact test specimens for the welding procedure qualification required by NC-4300 shall be made using the same minimum temperatures and increased minimum holding time. Welding procedures, qualified at the temperature range and minimum holding time specified in Table NC-4622.1-1 and at the lower temperature and increased minimum holding time permitted by Table NC-4622.4(c)-1, are also qualified for any temperature in between. When such an in-between temperature is used, the minimum holding time shall be interpolated from Table NC-4622.1-1 and the alternative requirements from Table NC-4622.4(c)-1.

(2) Except for P-No. 1 materials, when welds in the materials listed in Table NC-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the welding material certification required by NC-2400 shall be made using the same minimum temperature and increased minimum holding time. Welding material certified at the temperature range and minimum holding time specified in Table NC-4622.1-1 and at the lower minimum temperatures and increased minimum holding time permitted by Table NC-4622.4(c)-1 are also certified for any temperature in between.

(3) Base materials certified in accordance with NC-2200 may be postweld heat treated at these lower minimum temperatures and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation, provided a higher tempering temperature is not required by the material specification.

NC-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

When pressure retaining materials of two different P-Number groups are joined by welding, the applicable postweld heat treatment shall be that specified in Table NC-4622.1-1 for the material requiring the higher PWHT temperature range.

NC-4622.6 PWHT Requirements for Nonpressure- Retaining Parts.

When nonpressure-retaining materials are welded to pressure retaining materials, the postweld heat treatment temperature range of the pressure retaining materials shall control.

NC-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for (a) through (e) below:

(a) nonferrous materials;

(b) welds exempted in Table NC-4622.7(b)-1;

(c) welds subjected to temperatures above the PWHT temperature range specified in Table NC-4622.1-1, provided the Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld material have been heat treated at the higher temperature;

(d) welds connecting nozzles to components or branch to run piping, provided the requirements in NC-4622.8 are met;

(e) weld repairs to P-No. 3 materials in vessels, provided the requirements of NC-4622.9 are met.

NC-4622.8 Requirements for Exempting PWHT of Nozzles to Component Welds and Branch-to-Run Piping Welds.

Welds connecting nozzles or branch piping of P-No. 1 materials to components or run piping of P-No. 1 or P-No. 3 materials that are not exempted from PWHT in Table NC-4622.7(b)-1 need not be given a postweld heat treatment if the requirements of (a) are met for partial penetration and (b) are met for full penetration welds.

NOTES:

- (1) The exemptions noted in this Table do not apply to the following:
 - (a) electron beam welds in ferritic materials over $\frac{1}{8}$ in. in thickness;
 - (b) inertia and friction welds in material of any thickness of P-Nos. 3, 4, 5, 7 (except for Types 405 and 410 S), 10, and 11 materials.
- (2) Where the thickness of material is identified in the column Type of Weld, it is the thickness of the base material at the welded joint.
- (3) Carbon level of the pressure retaining materials being joined.
- (4) Maximum process heat input = 150,000 J/in. The maximum resulting hardness in the procedure qualification test plate shall not exceed 35 Rc.
- (5) Intermediate postweld soak at not less than 200°F for 2 hr minimum.
- (6) Intermediate postweld soak at not less than 300°F for 2 hr minimum.

TABLE NC-4622.7(b)-1 (CONT'D) EXEMPTIONS TO MANDATORY PWHT¹

(a) The partial penetration welds are made with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal after:

(1) the ferritic materials to be joined are buttered or built up with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal having a minimum thickness of $\frac{1}{4}$ in. (6 mm); and

(2) the heat affected zones of the buttered or built-up ferritic materials are postweld heat treated in accordance with NC-4620, without the PWHT exemptions being applied, prior to making the final welds.

(b) The full penetration welds are made with A-No. 1 or A-No. 2 weld metal, provided that:

(1) the component or run pipe is built up or buttered in the area of the attachment with A-No. 1 or A-No. 2 metal having a minimum thickness of $\frac{1}{4}$ in. (6 mm);

(2) the A-No. 1 or A-No. 2 weld metal buildup or buttering is postweld heat treated in accordance with NC-4620 for P-No. 1 or P-No. 3 materials without the PWHT exemptions being applied;

(3) the welds do not penetrate through the component or run pipe thickness;

(4) weld metal with A-No. 1 or A-No. 2 analysis is used to join the nozzle or branch pipe of P-No. 1 material to the weld buildup or buttering;

(5) the nominal thickness of the weld joining the nozzle or branch pipe to the component or run pipe does not exceed $1\frac{1}{2}$ in. (38 mm), and the maximum reported carbon content of the nozzle or branch piping connection does not exceed 0.30%;

(6) a 200°F (93°C) minimum preheat is maintained during welding whenever the nominal thickness of the weld exceeds:

(a) $1\frac{1}{4}$ in. (32 mm) and the maximum reported carbon content of the material of the nozzle or branch pipe is 0.30% or less; or

(b) $\frac{3}{4}$ in. (19 mm) and the maximum reported carbon content of material of the nozzle or branch pipe connection exceeds 0.30%.

NC-4622.9 Weld Repair to Vessels.

Limited weld repairs to vessels of P-No. 3 materials and A-No. 1, A-No. 2, A-No. 10, or A-No. 11 weld filler metal (Section IX, QW-442) may be made without PWHT or after the final PWHT, provided the requirements of the following subparagraphs are met:

(a) *Examination of Area to Be Repaired.* Before a repair is made, the area shall be examined by magnetic particle or liquid penetrant method in accordance with NC-5110 and shall meet the acceptance standards of NC-5340 or NC-5350, as appropriate.

(b) *Maximum Extent of Repairs.* A repair shall not exceed 10 sq in. in surface area and shall not be greater in depth than 50% of the base metal or weld thickness or $\frac{1}{2}$ in. (13 mm), whichever is less.

(c) *Repair Welding Procedure*

(1) The repairs shall be made using one or more procedures and welders qualified in accordance with Section IX and the requirements of this Subsection using the shielded metal-arc process and low hydrogen covered electrodes.

(2) The largest electrode diameter shall be $\frac{5}{32}$ in. (4 mm), and the bead width shall not exceed four times the electrode diameter.

(3) The repair weld shall be made with a minimum of two layers of weld metal. The last layer shall be limited or ground off so that the weld surface does not extend above the base metal a greater distance than that allowed for reinforcement of butt welds.

(4) A preheat and interpass temperature of 300°F (149°C) minimum shall be used.

(d) *Examination of Repair Welds.* Following the repair and when the area has reached ambient temperature, the area shall again be examined by magnetic particle methods and accepted in accordance with NC-4622.9(a) above.

NC-4623 PWHT Heating and Cooling Rate Requirements

Above 800°F (427°C), the rate of heating and cooling in any hourly interval shall not exceed 400°F divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°C) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 mm) interval of weld length. The exceptions of (a) and (b) below are permitted.

(a) P-No. 6 materials may be cooled in air from the postweld heat treatment holding temperature specified in Table NC-4622.1-1.

(b) For P-No. 7 materials the cooling rate at temperatures above 1200°F (649°C) shall not exceed 100°F/hr (56°C), after which the rate of cooling shall be sufficiently rapid to prevent embrittlement.

NC-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

Page 282

NC-4624.1 Furnace Heating - One Heat.

Heating the component or item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation, and direct impingement of flame on the component or item is prohibited.

NC-4624.2 Furnace Heating - More Than One Heat.

The component or item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of NC-4624.1 apply and that overlap of the heated sections of the component or item is at least 5 ft (1.5 m). When this procedure is used, the portion of the component or item outside the furnace shall be shielded so that the temperature gradient is not harmful. The cross section where the component or item projects from the furnace shall not intersect a nozzle or other structural discontinuity.

NC-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire component or item. Local postweld heat treatment shall consist of heating a circumferential band around the component or item at temperatures within the ranges specified in this Subarticle. The minimum width of the controlled band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the component or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs.

NC-4624.4 Heating Components Internally.

The component or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the component or item. Previous to this operation, the component or item should be fully enclosed with insulating material.

NC-4630 HEAT TREATMENT OF WELDS OTHER THAN THE FINAL POSTWELD HEAT TREATMENT

The holding temperature, the time at temperature, the heating rate, and the cooling rate need not conform to the requirements of this Article for heat treatments other than the final postweld heat treatment.

NC-4650 HEAT TREATMENT AFTER BENDING OR FORMING FOR PIPE, PUMPS, AND VALVES

NC-4651 Conditions Requiring Heat Treatment After Bending or Forming

(a) Ferritic alloy steel pipe or formed portions of pumps or valves that have been heated for bending or other forming operations shall receive a heat treatment in accordance with NC-4620, a full anneal, a normalizing and tempering treatment, or a quenching and tempering treatment.

(b) Carbon steel pipe or formed portions of pumps or valves with a wall thickness greater than $\frac{3}{4}$ in. (19 mm) included in group P-No. 1 in Section IX that have been cold bent or formed shall receive heat treatment in accordance with NC-4620.

(c) Ferritic alloy pipe or formed portions of pumps or valves with an outside diameter greater than 4 in. (102 mm) and a wall thickness greater than $\frac{1}{2}$ in. (13 mm) included in groups P-No. 3 through P-No. 5 in Section IX that have been cold bent or formed shall require a heat treatment in accordance with NC-4620.

NC-4652 Exemptions From Heat Treatment After Bending or Forming

If the conditions described in (a) through (d) are met, heat treatment after bending or forming is not required.

(a) Carbon steel pipe or portions of pumps and valves that have been bent or formed at a temperature of 1650°F or higher shall require no subsequent heat treatment, providing the requirements of NC-4213 have been met.

(b) Austenitic stainless steel pipe, or portions of pumps or valves that have been heated for bending or other forming operations, may be used in the as-bent condition, unless the Design Specifications require a heat treatment following bending or forming.

(c) Austenitic stainless steel pipe or portions of pumps or valves that have been cold bent or formed may be used in the as-bent condition, unless the Design Specifications require a heat treatment following bending or forming.

(d) Carbon steel and ferritic alloy-steel pipe or portions of pumps or valves with size and wall thicknesses less than specified in subparagraphs NC-4651(b) and (c) may be cold bent or formed without a heat treatment following bending.

Page 283

NC-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic material over $1\frac{1}{2}$ in. (38 mm) in thickness at the joints shall be given a grain refining heat treatment.

NC-4700 MECHANICAL JOINTS

NC-4710 BOLTING AND THREADING

NC-4711 Thread Engagement

The threads of all bolts or studs shall be engaged in accordance with the design.

NC-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the service conditions and shall not react unfavorably with either the service fluid or any component material in the system.

NC-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be seal-welded.

NC-4720 BOLTING FLANGED JOINTS

In bolting gasketed flanged joints, the contact faces of the flanges shall bear uniformly on the gasket and the gasket shall be properly compressed in accordance with the design principles applicable to the type of gasket used. All flanged joints shall be made up with relatively uniform bolt stress.

NC-4730 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

(a) Electrical and mechanical penetration assemblies, except those portions performing an electrical conducting or insulating function, shall be constructed in accordance with the rules for components.

(b) Tubes or pipes of 2 in. nominal pipe size (DN 50) and less may be joined to a penetration assembly in accordance with the rules of NC-4350.

(c) The closing seam for the penetration assembly may be made with a multipass single lap fillet weld as shown in Fig. NC-4730-1, provided the requirements of (1) through (5) below are met.

(1) One of the heads on the penetration assembly shall meet the requirements of NC-3352.3.

(2) The penetration assembly shall not exceed 18 in. (457 mm) outside diameter.

(3) The Design Pressure of the penetration assembly shall not exceed 100 psi (690 kPa) and the Design Temperature shall not exceed 400°F (204°C).

(4) Examination of the fillet weld shall be by the liquid penetrant method in accordance with NC-5350.

(5) The fillet weld and closure head shall meet the requirements of NC-3720(b).

NC-4800 EXPANSION JOINTS

NC-4810 FABRICATION AND INSTALLATION RULES FOR BELLOWS EXPANSION JOINTS

For bellows type expansion joints, the requirements of (a) through (f) below shall be met.

(a) All welded joints shall comply with the requirements of NC-4000.

(b) The longitudinal seam welds in the bellows shall be a butt type full penetration weld.

(c) The bellows of the expansion joint shall be attached to the welding ends or flange by circumferential welds of a butt type having a full penetration through the thickness of the bellows portion, as shown in Fig. NC-4810(c)-1.

(d) Other than the attachment welds, no circumferential welds are permitted in the bellows elements.

(e) Prior to installation of the expansion joint in the system, weld repairs shall not be permitted on parent material of the bellows.

(f) See NC-3649.2 for general requirements applicable to fabrication and installation.

FIG. NC-4730-1 PENETRATION ASSEMBLY

FIG. NC-4730-1 PENETRATION ASSEMBLY

SEC III D1 NC-5000

ARTICLE NC-5000 EXAMINATION

Page 285

NC-5100 GENERAL REQUIREMENTS FOR EXAMINATION

NC-5110 PROCEDURE, QUALIFICATION, AND EVALUATION

NC-5111 General Requirements

(a) Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article. Radiographic examination shall be by film radiography or real time radiography in accordance with Section V, Article 2, except that fluorescent screens are not permitted for film radiography, the geometric unsharpness shall not exceed the limits of T-285, and the penetrameters of Table NC-5111-1 shall be used in lieu of those shown in Table T-276. The requirements for the retention of radioscopic images are the same as for film radiography. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; liquid penetrant examination shall be in accordance with Section V, Article 6; and leak testing shall be in accordance with Section V, Article 10.

(b) Class 2 pressure vessels designed to the requirements of NC-3200 shall meet the requirements of NC-5250 in lieu of NC-5210 through NC-5240.

(c) Nondestructive examination requirements for tanks are given in NC-5280.

(d) The examinations required by this Article, or by reference to this Article, shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

NC-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedure shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radiosopic images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display and Storage for Radiography and Radioscopy". Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

NC-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination materials are applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable materials or procedure specifications.

NC-5120 TIME OF EXAMINATION OF WELDS AND WELD METAL CLADDING

Acceptance examinations of welds and weld metal cladding required by NC-5200 shall be performed at the times stipulated in (a) through (d) below during fabrication and installation.

(a) Radiographic examination of welds shall be performed after an intermediate¹ or final postweld heat treatment, when required, except as provided in (1) and (2) below.

¹ An intermediate postweld heat treatment for this purpose is defined as a postweld heat treatment performed on a weld within a temperature range not lower than the minimum holding temperature range to which the weld will be subjected during the final postweld heat treatment.

Page 290

Over 16–20	200	0.400	2T	0.320	120	0.240	2T	0.160

NOTE:

(1) Hole (plaque) type penetrators may be used on flat plates and on objects with geometries such that the penetrator hole image is not distorted.

TABLE NC-5111-1 THICKNESS, PENETRATOR DESIGNATIONS, AND ESSENTIAL HOLES, AND WIRE DIAMETERS

(1) Radiographic examination of welds in items fabricated of P-No. 1 materials may be performed prior to any required postweld heat treatment.

(2) Radiographic examination of welds in P-No. 3 materials may be performed prior to an intermediate or final postweld heat treatment provided the welds are ultrasonically examined after an intermediate or the final postweld heat treatment. The ultrasonic examination and acceptance standards shall be in accordance with this Article.

(b) Magnetic particle or liquid penetrant examinations of welds shall be performed after any required postweld heat treatment, except that welds in P-No. 1 materials may be examined either before or after postweld heat treatment.

(c) All dissimilar metal weld joints such as in austenitic or high nickel to ferritic material or using austenitic or high nickel alloy filler metal to join ferritic materials which penetrate the wall shall be examined after final postweld heat treatment.

(d) The magnetic particle or liquid penetrant examination of weld surfaces that are to be covered with weld metal cladding shall be performed before the weld metal cladding is deposited. The magnetic particle or liquid penetrant examination of weld surfaces that are not accessible after a postweld heat treatment shall be performed prior to the operation which caused this inaccessibility. These examinations may be performed before PWHT.

(e) Ultrasonic examination of electroslag welds in ferritic materials shall be performed after a grain refining heat treatment, when performed, or after final postweld heat treatment.

NC-5130 EXAMINATION OF WELD EDGE PREPARATION SURFACES

All full penetration weld edge preparation surfaces for joint Categories A, B, C, D, and similar joints in material 2 in. or more in thickness shall be examined by the magnetic particle or liquid penetrant method. Indications shall be evaluated in accordance with the acceptance standards of (a), (b), and (c) below.

(a) Only indications with major dimensions greater than $\frac{1}{16}$ in. shall be considered relevant imperfections.

(b) Laminar-type imperfections are acceptable without repair if they do not exceed 1 in. (25 mm) in

Page 291

length. The extent of all laminar-type imperfections exceeding 1 in. (25 mm) in length shall be determined by ultrasonic examination. Imperfections exceeding 1 in. (25 mm) in length shall be repaired by welding to a depth of $\frac{3}{8}$ in. (10 mm) or the depth of the imperfection, whichever is less, unless the ultrasonic examination reveals that additional depth of repair is required to meet the ultrasonic examination requirement for the product form.

(c) Indications of nonlaminar imperfections of (1) through (3) below are unacceptable:

(1) any linear indications greater than $\frac{3}{16}$ in. (4.8 mm) long;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more indications, in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less, edge to edge.

(d) Weld repairs made to weld edge preparations for Category A, B, C, D, and similar type welds shall be examined by the magnetic particle or liquid penetrant method before the surfaces become inaccessible. The examination may be performed before or after postweld heat treatment.

NC-5140 EXAMINATION OF OPENINGS CUT IN VESSELS DESIGNED TO NC-3200

For nozzle connections with necks abutting the vessel wall [Fig. NC-4266(b)-1 sketches (a) and (b)], the radially disposed surfaces of the openings cut in the vessel walls shall be examined by either magnetic particle method or a liquid penetrant method in accordance with the requirements of this Article. Defects thus discovered shall be removed and repaired as required by the applicable Article.

NC-5200 EXAMINATION OF WELDS²

NC-5210 CATEGORY A VESSEL WELDED JOINTS AND LONGITUDINAL WELDED JOINTS IN PIPING, PUMPS, AND VALVES

NC-5211 Vessel Welded Joints

(a) Category A welded joints shall be fully radiographed when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) thickness.

2 See NC-5250 for vessels designed to NC-3200. See NC-5280 for requirements for storage tank welds.

(b) Category A welded joint surfaces may be examined by either the magnetic particle or liquid penetrant method as an alternative to the radiographic examination when the thickness of each member being joined is $\frac{3}{16}$ in. (4.8 mm) or less.

NC-5212 Pipe, Pump, and Valve Welded Joints

Longitudinal butt welded joints, as defined in NC-3351.1, shall be radiographed.

NC-5220 CATEGORY B VESSEL WELDED JOINTS AND CIRCUMFERENTIAL WELDED JOINTS IN PIPING, PUMPS, AND VALVES

NC-5221 Vessel Welded Joints

(a) Category B welded joints shall be fully radiographed when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) thickness.

(b) Category B welded joint surfaces may be examined by either the magnetic particle or liquid penetrant method as an alternative to the radiographic examination when the thickness of each member being joined is $\frac{3}{16}$ in. (4.8 mm) or less.

NC-5222 Piping, Pump, and Valve Welded Joints

(a) Butt welded joints shall be radiographed.

(b) Fillet and partial penetration welded joints shall be examined by either the magnetic particle or liquid penetrant method.

NC-5230 CATEGORY C VESSEL WELDED JOINTS AND SIMILAR WELDED JOINTS IN OTHER COMPONENTS

(a) Category C full penetration butt welded joints and similar welded joints in other components shall be fully radiographed when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) of thickness.

(b) Category C full penetration corner welded joints and similar welded joints in other components shall be ultrasonically or radiographically examined when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) of thickness.

(c) Category C welded joint surfaces and similar welded joints in other components may be examined by either the magnetic particle or liquid penetrant method as an alternative to the radiographic or ultrasonic

Page 292

examination when the thickness of each member being joined is $\frac{3}{16}$ in. (4.8 mm) or less.

(d) Category C partial penetration and fillet welded joints and similar welded joints in other components shall be examined by the magnetic particle or liquid penetrant method on all accessible surfaces.

NC-5240 CATEGORY D VESSEL WELDED JOINTS AND SIMILAR WELDED JOINTS IN OTHER COMPONENTS

NC-5241 Vessel Welded Joints

(a) Category D full penetration butt welded joints and similar welded joints in other components shall be fully radiographed when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) of thickness.

(b) Category D full penetration corner welded joints and similar welded joints in other components shall be ultrasonically or radiographically examined when either of the members being joined exceeds $\frac{3}{16}$ in. (4.8 mm) of thickness.

(c) Category D welded joint surfaces and similar welded joints in other components may be examined by either the magnetic particle or liquid penetrant method as an alternative to the radiographic or ultrasonic examination when the thickness of each member being joined is $\frac{3}{16}$ in. (4.8 mm) or less.

(d) Category D partial penetration and fillet welded joints and similar welded joints in other components shall be examined by the magnetic particle or liquid penetrant method on all accessible surfaces.

NC-5242 Welded Branch Connections³ and Nozzles in Piping, Pumps, and Valves

(a) Branch connections³ and nozzles with nominal pipe size exceeding 4 in. shall be examined by radiography.

(b) Branch connections³ and nozzles with nominal pipe size 4 in. and smaller shall have the external weld surface and the accessible internal weld surface examined by either the magnetic particle or liquid penetrant method.

³ Welds in branch piping runs shall be examined as required by NC-5212 and NC-5222.

NC-5250 EXAMINATION OF WELDS FOR VESSELS DESIGNED TO NC-3200

NC-5251 Category A Welded Joints

Category A welded joints shall be fully radiographed.

NC-5252 Category B Welded Joints

Category B welded joints shall be fully radiographed.

NC-5253 Category C Welded Joints

(a) Category C full penetration butt welded joints shall be fully radiographed.

(b) Category C full penetration corner welded joints shall be ultrasonically or radiographically examined.

(c) Category C partial penetration or fillet welded joints shall be examined by either the liquid penetrant or magnetic particle method on all accessible surfaces.

(d) For corner joint constructions as illustrated in Fig. NC-4265-1 sketches (b) and (c), except when dimension b is equal to or greater than t_s , the unstayed flat head, prior to welding, shall be 100% examined by the ultrasonic method in accordance with the requirements of SA-435, except that no lamination in the head is acceptable.

NC-5254 Category D Welded Joints

(a) Category D full penetration butt welded joints shall be fully radiographed.

(b) Category D full penetration corner welded joints shall be ultrasonically or radiographically examined.

(c) Category D partial penetration or fillet welded joints shall be examined by either the liquid penetrant or magnetic particle method on all accessible surfaces.

NC-5257 Other Welded Joints for Vessels Designed to NC-3200

The requirements of NC-5260, NC-5270, and NC-5410 also apply to vessels designed to NC-3200.

NC-5260 FILLET, PARTIAL PENETRATION, SOCKET, AND ATTACHMENT WELDS

NC-5261 Fillet, Partial Penetration, and Socket Welded Joints

shall be examined by the magnetic particle or liquid penetrant method.

NC-5262 Structural Attachment Welded Joints

Structural attachment welded joints made to pressure retaining material shall be examined by either the magnetic particle or liquid penetrant method.

NC-5270 SPECIAL WELDS

NC-5271 Welds of Specially Designed Seals

Welds of this type shall be examined by either the magnetic particle or liquid penetrant method.

NC-5272 Weld Metal Cladding

Weld metal cladding shall be examined by the liquid penetrant method.

NC-5273 Hard Surfacing

Hard surfacing shall be examined by the liquid penetrant method in accordance with NC-2546, and the acceptance standards applicable to materials less than $\frac{5}{8}$ in. (16 mm) thick shall apply. Penetrant examination is not required for hard surfacing on valves with inlet connections 4 in. nominal pipe size (DN 100) or less.

NC-5274 Tube-to-Tubesheet Welds

Tube-to-tubesheet welds shall be examined by the liquid penetrant method.

NC-5275 Brazed Joints

Flux and flux residue shall be removed from all surfaces prior to examination. Joints shall be visually examined on all accessible surfaces to determine whether there has been adequate flow of brazing metal through the joint. Optical aids may be employed for indirect visual examination of joints which cannot be directly examined.

NC-5276 Inertia and Continuous Drive Friction Welds

(a) When radiographic examination is required by this Article, inertia and continuous drive friction welds shall also be examined by the ultrasonic method to verify bonding over the entire area.

(b) The materials used shall be those assigned a P-Number by Section IX, but shall not include rimmed or semikilled steel.

(c) One of the two parts to be joined must be held in a fixed position and the other part rotated. The two faces to be joined must be symmetrical with respect to the axis of rotation.

(d) The weld between the two members shall be a full penetration weld.

NC-5278 Electroslag Welds

In addition to the requirements for the type of weld being examined, all complete penetration welds made by the electroslag welding process in ferritic materials shall be ultrasonically examined.

NC-5279 Special Exceptions

When the joint detail does not permit radiographic examination of joints attaching penetration assemblies, which are fabricated as appurtenances, or the closing seam within an electrical penetration assembly, which is not fabricated as an appurtenance, ultrasonic examination plus liquid penetrant or magnetic particle examination of the completed weld may be substituted for the radiographic examination. The absence of suitable radiographic equipment shall not be justification

be substituted for the radiographic examination. The absence of suitable radiographic equipment shall not be justification for such substitution. The substitution of ultrasonic examination can be made, provided the examination is performed using a detailed written procedure which has been proven by actual demonstration to the satisfaction of the Inspector as capable of detecting and locating defects described in this Subsection. The nondestructive examination shall be in accordance with Section V and meet the acceptance standards of NC-5300.

NC-5280 WELD JOINTS IN STORAGE TANKS

NC-5281 Examination Procedures

Nondestructive examinations of welds in storage tanks shall be in accordance with the examination procedures of Section V.

NC-5282 Atmospheric Storage Tanks

NC-5282.1 Sidewall Joints.

Sidewall joints shall be fully radiographed.

Page 294

NC-5282.2 Roof Joints and Roof-to-Sidewall Joints.

Roof joints and roof-to-sidewall joints shall be examined visually.

NC-5282.3 Bottom Joints.

Bottom joints shall be examined from the inside of the tank by applying soapsuds to the joints and pulling a partial vacuum of at least 3 psi by means of a vacuum box with transparent top.

NC-5282.4 Bottom-to-Sidewall Joints.

Bottom-to-sidewall joints shall be examined by the vacuum box method as detailed in NC-5282.3 and by a magnetic particle or liquid penetrant surface examination.

NC-5282.5 Nozzle-to-Tank Joints.

Nozzle-to-sidewall or bottom joints shall be examined by either the magnetic particle or liquid penetrant method. Nozzle-to-roof joints shall be visually examined.

NC-5282.6 Joints in Nozzles.

All joints in roof nozzles shall be visually examined. Butt joints in other nozzles shall be examined by the radiographic method; other types of nozzle joints shall be examined by the liquid penetrant or magnetic particle method.

NC-5282.7 Other Joints.

Joints not specifically covered by NC-5282 shall be examined in the same manner as similar weld joints in vessels as required by this Subarticle.

NC-5283 Weld Joints in 0-15 psi (0-103 kPa) Storage Tanks

NC-5283.1 Sidewall Joints.

Sidewall joints shall be fully radiographed.

NC-5283.2 Roof Joints.

Roof joints shall be fully radiographed.

NC-5283.3 Roof-to-Sidewall Joints.

Roof-to-sidewall joints shall be fully radiographed if the design permits. If not radiographed, these joints shall be examined by the magnetic particle or liquid penetrant method.

NC-5283.4 Bottom Joints.

Joints in bottoms supported directly on grade shall be examined by the vacuum box method as detailed in NC-5282.3. Joints not supported directly on grade shall be fully radiographed.

NC-5283.5 Bottom-to-Sidewall Joints.

Bottom-to-sidewall joints shall be examined by the vacuum box method as detailed in NC-5282.3 and by either the magnetic particle method or the liquid penetrant method.

NC-5283.6 Nozzle-to-Tank Joints.

Nozzle-to-tank joints shall be examined by either the magnetic particle or liquid penetrant method.

NC-5283.7 Joints in Nozzles.

Butt joints in nozzles shall be fully radiographed. Other joints shall be examined by magnetic particle or liquid penetrant methods.

NC-5283.8 Other Joints.

Joints not specifically covered by NC-5283 shall be examined in the same manner as similar weld joints in vessels as required by this Subarticle.

NC-5300 ACCEPTANCE STANDARDS

NC-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following conditions:

- (a) any indication characterized as a crack or zone of incomplete fusion or penetration;
- (b) any other elongated indication which has a length greater than:
 - (1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. to $2\frac{1}{4}$ in. (19 mm to 57 mm), inclusive
 - (3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the thinner portion of the weld.

(c) Internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable as provided in (b) above;

(d) any group of aligned indications having an aggregate length greater than t in a length of $12t$ unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(e) rounded indications in excess of those shown as acceptable in Appendix VI.

NC-5330 ULTRASONIC ACCEPTANCE STANDARDS

All imperfections which produce a response greater than 20% of the reference level shall be investigated to the extent that the operator can determine the shape, identity, and location of all such imperfections and evaluate them in terms of the

(a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:

- (1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
- (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. to $2\frac{1}{4}$ in. (19 mm to 57 mm), inclusive
- (3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

NC-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

NC-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are those which result from imperfections. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NC-5342 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (645 mm²) of surface, with the major dimension of this area not to exceed 6 in. (152 mm), with the area taken in the most unfavorable location relative to the indications being evaluated.

NC-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

NC-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks, surface conditions, or an incomplete bond between base metal and cladding may produce similar indications which are nonrelevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are those which result from imperfections. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NC-5352 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks or linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (645 mm²) of surface, with the major dimension of this area not to exceed 6 in. (152 mm), with the area taken in the most unfavorable location relative to the indications being evaluated.

Page 296

NC-5360 VISUAL ACCEPTANCE STANDARDS FOR BRAZED JOINTS

Braze metal shall give evidence of having flowed uniformly through a joint by the appearance of an uninterrupted, narrow visible line of brazing alloy at the ends of the joint.

NC-5370 ACCEPTANCE STANDARDS FOR METALLOGRAPHIC EXAMINATION OF SPECIALLY DESIGNED WELDED SEALS

(a) Each cross section of the qualification test assembly (NC-4367) for specially designed welded seals shall be examined at $\times 10$ to $\times 15$, in accordance with the ASTM Standard E 2.

(b) All surfaces shall be free of cracks, incomplete penetration, incomplete melting of insert on consumable type welds, and rounded indications or inclusions in excess of one rounded void with the maximum dimension not greater than 10% of the thickness of the weld.

NC-5380 GAS AND BUBBLE FORMATION TESTING

For gas and bubble formation testing, the test procedure shall be in accordance with T-1030 of Section V, Article 10. When vacuum box testing is used, the soak time shall be a minimum of 10 sec. Any indication of leaking, by the formation of bubbles or the breaking of the continuous soap film by leaks, shall be evidence of an unacceptable condition.

NC-5400 FINAL EXAMINATION OF COMPONENTS

NC-5410 EXAMINATION AFTER PRESSURE TESTING

After the required pressure test of a component constructed of ferritic materials with properties enhanced by quenching and tempering, all pressure retaining welded joints shall be examined by the magnetic particle or liquid penetrant method on all accessible surfaces.

NC-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

NC-5510 GENERAL REQUIREMENTS

Organizations performing Code required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by NC-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of NC-5520. All nondestructive examinations required by this Subsection shall be performed by and the results evaluated by qualified nondestructive

examination personnel.

NC-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

NC-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended guidelines of SNT-TC-1A.⁴⁵ The Employer's⁶ written practice required by paragraph 5 of SNT-TC-1A shall identify his requirements relative to the recommended guidelines. The recommended guidelines of SNT-TC-1A shall be considered minimum requirements, except as modified in (1) through (5) below.

(1) Qualification of Level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by the Employer, ASNT, or an outside agency.

4 SNT-TC-1A is a Recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, Ohio 43228-0518. SNT-TC-1A-1992 is the applicable edition.

5 Personnel qualified by examination and certified to previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

6 Employer as used in this Article shall include: N Certificate Holders; Quality System Certificate Holders; Material Manufacturers and Material Suppliers who are qualified in accordance with NCA-3862(a)(1); and organizations who provide subcontracted nondestructive examination services to organizations described above.

(b) The specific examination, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by

Page 297

the Employer or an outside agency. The Employer or outside agency administering the specific examination shall identify the minimum grade requirement in the written program when the basic and method examinations have been administered by ASNT, which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The training and experience times shall be described in the written practice, and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

(a) The minimum classroom training times identified in Table 6.3.1 of SNT-TC-1A may be reduced from 8 and 16 hours to 4 and 8 hours, respectively for visual examination personnel.

(4) or visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in the written instructions.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subsection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use

personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

NC-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of Levels I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [NC-5521(a)(2)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

NC-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Manufacturers and Material Suppliers qualified by them in accordance with NCA-3820 and subcontractors who provide nondestructive examination services to them.

NC-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

NC-5700 EXAMINATION REQUIREMENTS FOR EXPANSION JOINTS

NC-5720 BELLOWS EXPANSION JOINTS

The examinations stipulated in (a) through (f) below are required to verify the integrity of bellows expansion joints for installation in components.

(a) The formed bellows shall be determined to be free of defects such as notches, crevices, material buildup or upsetting, weld spatter, etc., by visual examination. Suspect surface areas shall be further examined by liquid penetrant examination in accordance with NC-5110.

(b) The longitudinal seam welds in the bellows shall be examined by the liquid penetrant method in accordance with NC-5110. When the individual ply thickness

Page 298

exceeds $\frac{1}{8}$ in. (3.2 mm), the weld shall also be radiographed in accordance with NC-5110. These examinations may be performed either before or after the bellows is formed.

(c) The circumferential attachment welds between the bellows and pipe or flange shall be liquid penetrant examined in accordance with NC-5110 when the total bellows thickness is $\frac{1}{4}$ in. (6 mm) or less. When the total thickness exceeds this limit, the weld shall be radiographed in accordance with NC-5110 except where radiography is not meaningful, such as when the weld thickness constitutes less than 20% of the total thickness being radiographed, liquid penetrant examination may be substituted.

(d) In the case of liquid penetrant examination of bellows welds, imperfections producing the following indications are unacceptable:

(1) cracks or linear indications;

(2) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(3) five or more randomly distributed rounded indications in a weld length of 6 in. (152 mm);

(4) any rounded indication exceeding the lesser of one-half the bellows thickness or $\frac{1}{16}$ in. (1.6 mm) in diameter.

(e) The examination of all other welds in the expansion joint shall comply with NC-5000.

(f) The variation of the cylindrical end thickness of the formed bellows from the nominal or specified thickness shall not exceed the values given in Table 2 of SA-480. Thinning of the bellows material during forming shall be considered in the design and selection of material thickness, but need not be limited to the values specified in Table 2 of SA-480.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NC-6000

ARTICLE NC-6000 TESTING

Page 299

NC-6100 GENERAL REQUIREMENTS

NC-6110 PRESSURE TESTING OF COMPONENTS, APPURTENANCES, AND SYSTEMS

NC-6111 Scope of Pressure Testing

All pressure retaining components, appurtenances, and completed systems shall be pressure tested, except as specified in (a) through (d) below. Portions of piping systems which are exempt shall be identified in the Design Specification and the N-5 Data Report Form. The Design Specification shall be available to the Authorized Nuclear Inspector when the balance of the system is hydrostatically tested.

(a) Bolts, studs, nuts, washers, and gaskets are exempt.

(b) The following portions of piping systems whose only function is to transport fluids to and from spray ponds, lakes, reservoirs, or tanks which are open to the atmosphere are exempt:

(1) piping downstream of the last isolation valve preceding the pipe discharge to the spray pond, lake, reservoir, or tank; and

(2) piping upstream of the intake pump inlet isolation valve.

(c) Where systems discharge into Class 2 vessels, or the gaseous regions of MC containment vessels through spargers or spray nozzles, only that portion of the system external to the vessel is required to be pressure tested.

(d) The portion of a Class 2 safety and safety relief valve discharge piping that is submerged below the minimum Design Level in a containment pressure suppression pool of an MC or CC containment vessel is exempt. The minimum Design Level shall be specifically designated in the Design Specification.

NC-6112 Pneumatic Testing

A pneumatic test in accordance with NC-6300 may be substituted for the hydrostatic test when permitted by NC-6112.1 (a).

NC-6112.1 Pneumatic Test Limitations

(a) A pneumatic test may be used in lieu of a hydrostatic test only when any of the following conditions exist:

(1) when components, appurtenances, or systems are so designed or supported that they cannot be safely filled with liquid¹

(2) when components, appurtenances, or systems which are not readily dried are to be used in services where traces of the testing medium cannot be tolerated.

(b) A pneumatic test at a pressure not to exceed 25% of the Design Pressure may be applied, prior to either a hydrostatic or a pneumatic test, as a means of locating leaks.

NC-6112.2 Precautions to Be Employed in Pneumatic Testing.

Compressed gaseous fluid is hazardous when used as a testing medium. Therefore, it is recommended that special precautions for protection of personnel be taken when a gaseous fluid under pressure is used as a test medium.

NC-6113 Witnessing of Pressure Tests

Pressure testing required by this Article shall be performed in the presence of the Inspector, except that testing of each line valve and each pump having piping connections of NPS 4 (DN 100) and less need not be witnessed by the Inspector. For line valves and pumps NPS 4 and less, the Inspector's review and acceptance of the Certificate Holder's test records will be authorization to sign the Data Report Form, and takes precedence over NCA-5280.

NC-6114 Time of Pressure Testing

NC-6114.1 System Pressure Test.

The installed system shall be pressure tested prior to initial operation.

1 These tests may be made with the item being tested partially filled with liquid, if desired.

Page 304

The pressure test may be performed progressively on erected portions of the system.

NC-6114.2 Component and Appurtenance Pressure Test

(a) Components and appurtenances shall be pressure tested prior to installation in a system, except as permitted in (b) below.

(b) The system pressure test may be substituted for a component or appurtenance pressure test, provided:

(1) the component can be repaired by welding in accordance with the rules of NC-4130 and NC-4450, if required, as a result of the system pressure test;

(2) the component repair weld can be postweld heat treated in accordance with NC-4620, if required, and nondestructively examined in accordance with the rules of NC-4130 and NC-4450, as applicable; and

(3) the component is resubjected to the required system pressure test following the completion of repair and examination if the repair is required to be radiographed by NC-4453.4.

(c) Valves require pressure testing prior to installation in a system in accordance with NC-3500.

(d) Items which, when assembled, form a completed pump or valve may be tested in the form of subassemblies, provided:

(1) the test pressure is in accordance with the requirements of NC-6221;

(2) the pressure test is performed in a manner which, in the subassembly under test, will simulate the loadings present when the completed pump or valve is assembled and pressurized;

(3) the component Certificate Holder approves any pressure test of component subassemblies;

(4) the component Certificate Holder specifies the pressure test requirements and test pressure to be used;

(5) each subassembly pressure test is performed by a Certificate Holder and is performed in the presence of the Authorized Nuclear Inspector;

(6) each subassembly pressure tested by other than the component Certificate Holder is stamped with the NPT symbol, except as provided in NCA-8330; the test pressure shall be identified on the Partial Data Report Form;

(7) each subassembly pressure tested by other than the component Certificate Holder is listed on the Code Data Report Form;

- (8) the pressure tested subassemblies of pumps or valves are subsequently assembled by mechanical methods only;
- (9) welds examined during the subassembly pressure test need not be reexamined during the system pressure test.

NC-6114.3 Material Pressure Test.

The component or appurtenance pressure test may be used in lieu of any such test required by the material specification for a part or material used in the component or appurtenance, provided:

- (a) nondestructive examinations, if required by the material specification, can be performed subsequent to the component or appurtenance pressure test;
- (b) the material can be repaired by welding in accordance with the rules of NC-4130 if required as a result of the pressure test; and
- (c) postweld heat treatment, when required after repairs, can be performed in accordance with NC-4620.

NC-6115 Machining After Pressure Test

An additional amount of material, not to exceed 10% of the wall thickness or $\frac{3}{8}$ in. (10 mm), whichever is less, is permitted on the completed component during pressure testing where machining to critical dimensions and tolerances is required.

NC-6120 PREPARATION FOR TESTING

NC-6121 Exposure of Joints

All joints, including welded joints, shall be left uninsulated and exposed for examination during the test.

NC-6122 Addition of Temporary Supports

Components designed to contain vapor or gas may be provided with additional temporary supports, if necessary, to support the weight of the test liquid.

NC-6123 Restraint or Isolation of Expansion Joints

Expansion joints shall be provided with temporary restraints, if required, for the additional pressure load under test.

NC-6124 Isolation of Equipment Not Subjected to Pressure Test

Equipment that is not to be subjected to the pressure test shall be either disconnected from the component or system or isolated during the test by a blind flange or similar means. Valves may be used if the valves with their closures are suitable for the proposed test pressure.

Page 305

NC-6125 Treatment of Flanged Joints Containing Blanks

Flanged joints at which blanks are inserted to isolate other equipment during the test need not be retested.

NC-6126 Precautions Against Test Medium Expansion

If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure.

NC-6127 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all low pressure filling lines and other items that should not be subjected to the test have been disconnected or isolated.

NC-6200 HYDROSTATIC TESTS

The requirements of this paragraph apply to all components except tanks, for which NC-6500 applies.

NC-6210 HYDROSTATIC TEST PROCEDURE

NC-6211 Venting During Fill Operation

The component or system in which the test is to be conducted shall be vented during the filling operation to minimize air pocketing.

NC-6212 Test Medium and Test Temperature

(a) Water or an alternative liquid, as permitted by the Design Specification, shall be used for the hydrostatic test.

(b) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture. The test pressure shall not be applied until the component, appurtenance, or system and the pressurizing fluid are at approximately the same temperature.

NC-6220 HYDROSTATIC TEST PRESSURE REQUIREMENTS

NC-6221 Minimum Hydrostatic Test Pressure

(a) The installed system shall be hydrostatically tested at not less than 1.25 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of NC-7000.

(b) Vessels designed in accordance with NC-3200 shall be hydrostatically tested at not less than 1.25 times the Design Pressure.

(c) Valves shall be hydrostatically tested in accordance with the rules of NC-3500.

(d) Other components, excluding piping systems, shall be hydrostatically tested at not less than 1.50 times their Design Pressure.

(e) As an alternative to NC-6221(a) above, piping between the discharge side of a centrifugal pump and the first shutoff valve may be hydrostatically tested at the shutoff head of the pump. The pressure shall be maintained for a sufficient time to permit examination of all joints, connections, and regions of high stress.

NC-6222 Maximum Permissible Pressure

(a) If the minimum test pressure of NC-6221(a) or (d) is to be exceeded by 6% at any location, the upper limit shall be established by analysis using all loadings that may exist during the test.

(b) For vessels designed to NC-3200, the stress limits of NC-3218 shall be used in determining the maximum permissible pressure.

(c) When testing a system, the test pressure shall not exceed the maximum permissible test pressure of any component in the system.

NC-6223 Hydrostatic Test Pressure Holding Time

The hydrostatic test pressure shall be maintained a minimum of 10 min prior to initiation of the examination for leakage required by NC-6224.

NC-6224 Examination for Leakage After Application of Pressure

Following the application of the hydrostatic test pressure for the required time (NC-6223), all joints, connections, and regions of high stress such as regions around openings and thickness transition sections shall be examined for leakage. Except in the case of pumps and valves, which shall be examined while at test

pressure, this examination shall be made at a pressure equal to the greater of the Design Pressure or three-fourths of the test pressure, and it shall be witnessed by the Inspector. Leakage of temporary gaskets and seals, installed for the purpose of conducting the hydrostatic test, and which will be replaced later, may be permitted unless the leakage exceeds the capacity to maintain system test pressure for the required amount of time. Other leaks, such as from permanent seals, seats, and gasketed joints in components, may be permitted when specifically allowed by the Design Specifications. Leakage from temporary seals or leakage permitted by the Design Specification shall be directed away from the surface of the component to avoid masking leaks from other joints.

NC-6230 BELLOWS EXPANSION JOINTS

The hydrostatic test requirements for bellows expansion joints shall be as required in (a) through (c) below.

(a) The completed expansion joint shall be subjected to a hydrostatic test in accordance with the applicable provisions of this Article as supplemented by the Design Specifications.

(b) This test may be performed with the bellows fixed in the straight position, at its neutral length, when the design has been shown to comply with NC-3649.4(e)(1) or (e)(2). If the design is to comply with NC-3649.4(e)(3), this test shall be performed with the bellows fixed at the maximum design rotation angle or offset movement.

(c) In addition to inspecting the expansion joint for leaks and general structural integrity during the test, the Inspector shall also visually inspect the bellows for evidence of meridional yielding as defined in NC-3649.4(b) and for evidence of squirm as defined in NC-3649.4(c). If the design is to comply with NC-3649.4(e)(3), actual measurements shall be made before, during, and after the pressure test in accordance with NC-3649.4(b) and (c).

NC-6240 PROVISION FOR EMBEDDED OR INACCESSIBLE WELDED JOINTS IN PIPING

When welded joints in piping subassemblies or piping systems will be embedded or are otherwise inaccessible for inspection at the time of the system hydrostatic test, either of the following alternatives may be employed. Alternative (b) does not apply to brazed joints.

(a) The piping subassembly, or portion of the piping system which is to be embedded, or will be otherwise inaccessible, shall be hydrostatically tested at some point in the fabrication or installation prior to embedment or inaccessibility.

(b) Radiography shall be performed on all circumferential butt welds, and either magnetic particle or liquid penetrant examination shall be performed on all fillet or socket welds in accordance with the requirements of NC-5000. The longitudinal butt welds shall meet the requirements of NC-2000. The hydrostatic test may then be performed after embedment, using maintenance of pressure as the acceptance criterion for those welds only. The system shall be pressurized to the hydrostatic test pressure and then isolated from the pressurizing source for a period of 1 hr/in. of wall thickness but not less than 1 hr. During the test period, there shall be no drop in pressure.²

NC-6300 PNEUMATIC TESTS

NC-6310 PNEUMATIC TESTING PROCEDURES

NC-6311 General Requirements

When a pneumatic test is performed, it shall be conducted in accordance with the requirements of NC-6100 and this Subarticle.

NC-6312 Test Medium and Test Temperature

(a) The gas used as the test medium shall be nonflammable.

(b) Testing temperature shall be in accordance with NC-6212(b).

NC-6313 Procedure for Applying Pressure

The pressure in the system shall be gradually increased to not more than one-half of the test pressure, after which the

The pressure in the system shall be gradually increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached.

2 Temperature fluctuations within the piping system may affect the pressure. Precautions must be taken to ensure that the test is not biased by temperature effects.

Page 307

NC-6320 PNEUMATIC TEST PRESSURE REQUIREMENTS

NC-6321 Minimum Required Pneumatic Test Pressure

(a) The installed system shall be pneumatically tested at not less than 1.25 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of NC-7000.

(b) Valves shall be pneumatically tested in accordance with the rules of NC-3500.

(c) Components shall be pneumatically tested at not less than 1.25 times their Design Pressure.

NC-6322 Maximum Permissible Test Pressure

The maximum test pressure shall be limited as defined in NC-6222.

NC-6323 Test Pressure Holding Time

The test pressure of NC-6321 shall be maintained for a minimum total time of 10 min.

NC-6324 Examination for Leakage After Application of Pressure

Following the application of pressure for the time specified in NC-6323, the test pressure shall be reduced to a value equal to the greater of the Design Pressure or three-fourths of the test pressure, and held for a sufficient time to permit examination as defined in NC-6224.

NC-6330 BELLOWS EXPANSION JOINTS

When a pneumatic test is performed on a bellows expansion joint in lieu of a hydrostatic test, the requirements of NC-6230 shall be met.

NC-6400 PRESSURE TEST GAGES

NC-6410 REQUIREMENTS FOR PRESSURE TEST GAGES

NC-6411 Types of Gages to Be Used and Their Location

Pressure test gages used in pressure testing shall be indicating pressure gages and shall be connected directly to the component. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator throughout the duration of the test. For systems with a large volumetric content, it is recommended that a recording gage be used in addition to the indicating gage.

NC-6412 Range of Indicating Pressure Gages

(a) Analog-type indicating pressure gages used in testing shall be graduated over a range not less than $1\frac{1}{2}$ times nor more than 4 times the test pressure.

(b) Digital-type pressure gages may be used without range restriction provided the combined error due to calibration and readability does not exceed 1% of the test pressure.

NC-6413 Calibration of Pressure Test Gages

All test gages shall be calibrated against a standard dead-weight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests, using the same pressure test gage or gages, which are conducted within a period not exceeding 2 weeks.

NC-6500 ATMOSPHERIC AND 0-15 psi STORAGE TANKS

NC-6510 TESTING OF ATMOSPHERIC STORAGE TANKS

NC-6511 Testing of Reinforcement Pads

Following the examination specified in NC-5282.5 and before filling the tank with test water, the reinforcement pads shall be tested by applying up to 15 psi pneumatic pressure between the tank shell and the reinforcement plate on each opening, using the telltale hole; and while each such space is subject to such pressure, soapsuds, linseed oil, or other suitable material for detection of leaks shall be applied to all attachment welding around reinforcement, both inside and outside the tank.

NC-6512 Preparation for Testing

Preparation for testing of storage tanks shall conform to the requirements of NC-6120, as applicable. Flat bottoms supported directly on grade need not comply with NC-6121.

Page 308

NC-6513 Hydrostatic Testing of Tank Shell

Upon completion of the tank, the shell shall be tested. For tanks with supported cone, self-supported cone, self-supported dome, and self-supported umbrella roofs, the tank shall be filled with water and inspected frequently during the filling operation. The filling height shall be 2 in. (51 mm) above the top leg of the angle. For tanks with flat roofs, the filling height shall be the liquid level for which the tank was designed or the bottom of any overflow which limits the filling height.

NC-6520 TESTING OF 0-15 psi STORAGE TANKS

NC-6521 Testing of Reinforcement Pads

Following the examination specified in NC-5282.5 and before performing the preliminary pneumatic testing, the reinforcement pads shall be tested by using the same procedure as given in NC-6511.

NC-6522 Preparation for Testing

Preparation for testing of storage tanks shall conform to the requirements of NC-6120, as applicable. Flat bottoms supported directly on grade need not comply with NC-6121.

NC-6523 Preliminary Pneumatic Testing

Prior to the application of the hydrostatic or combination hydrostatic pneumatic test, the tank shall be filled with air to a pressure of 2 psi (13.8 kPa) or one-half the pressure P_G for which the vapor space at the top of the tank is designed, whichever pressure is the smaller. Soapsuds shall be applied to all joints in the tank wall above the high liquid design level. If any leaks appear, the defective condition shall be corrected and the applicable preliminary tightness test shall be repeated. In the case of a tank whose bottom rests directly on the tank grade without having anchor bolts provided near the boundary of contact to hold it down, if the bottom at this boundary rises slightly off the foundation during the tightness test with air pressure in the tank, sand shall be tamped firmly under the bottom, while the tank is under pressure, to fill the gap so formed.

NC-6524 Combination Hydrostatic Pneumatic Tests

The following requirements apply to tanks which have not been designed to be filled with liquid to a test level higher than their specified capacity level.

NC-6524.1 Pressurizing.

After the preliminary tests specified in NC-6523 have been completed, the pressure relief valve or valves shall be blanked off. With the top of the tank vented to atmosphere to prevent accumulation of pressure, the tank shall be filled with water to its high liquid level. The vents at the top of the tank shall then be closed, and air shall be injected slowly into the top of the tank until the pressure in the vapor space is about one-half the pressure P_G for which this space is designed. Thereafter, the test pressure shall be increased in steps of approximately 2 psi (13.8 kPa) or one-fourth of the intended test pressure, whichever is the smaller, until the pressure in the vapor space is 1.25 times the pressure P_G for which this space is designed. Means shall be provided so that the required test pressure will not be exceeded.

NC-6524.2 Time at Pressure.

The pressure in the tank shall be held stationary for a reasonable time after the application of each increment of pressure as specified so as to provide an opportunity to examine the tank carefully for signs of distress. The maximum test pressure of 1.25 times the vapor space design pressure shall be held for at least 1 hr, after which the pressure shall be reduced slowly to the vapor space design pressure.

NC-6524.3 Soap Bubble Test.

The vapor space design pressure shall be held for a sufficient time to permit a close visual examination of all joints in the walls of the tank and of all welding around manways, nozzles, and other connections. In this examination, soapsuds shall be applied to all weld joints located above the high liquid design level for which the tank is designed, including the roof-to-sidewall joint. This examination is not required for welds subject to radiography.

NC-6524.4 Precautions to Be Employed in Pneumatic Testing.

An air test, as specified in NC-6523 and in NC-6524, introduces some hazard. In view of the large amount of air which will be present during such a test, it is recommended that no one be permitted to go near the tank while the pressure is being applied for the first time in this test. While the pressure in the tank exceeds the pressure for which the vapor space is designed, the inspections should be made from a

Page 309

reasonable distance from the tank using optical aids, if necessary, for observations of particular areas.

NC-6525 Hydrostatic Test

The following requirements apply to tanks which have been designed and constructed to be filled with liquid to the top of the roof.

NC-6525.1 Filling.

Following the preliminary tests specified in NC-6523, the pressure relief valve or valves shall be blanked off. With the top of the tank vented to atmosphere, the tank shall be filled with water to the top of the roof, while allowing all air to escape in order to prevent accumulation of pressure. The vents on the tank shall be closed, and the pressure in the tank shall be increased slowly until the hydrostatic pressure under the topmost point in the roof is 1.25 times the pressure P_G for which the vapor space is designed to withstand when in operation with the tank filled to its specified high liquid level.

NC-6525.2 Pressurizing.

Test pressure may be developed by (a) or (b) below:

(a) pumping water into the tank with all vents closed;

(b) superimposing a vertical pipe, not less than 6 in. nominal pipe size, above the top of the tank with an overflow located at such a height as to give the desired test pressure by static head alone and then filling the pipe to the level of said overflow.

NC-6525.3 Time at Pressure.

Test pressure shall be held for at least 1 hr. The hydrostatic pressure under the roof shall then be reduced to the Design Pressure and shall be held at this level for a sufficient time to permit close visual examination of all joints in the walls of the tank and of all welding around manways, nozzles, and other connections.

NC-6526 Partial Vacuum Testing Procedure

NC-6526.1 Development of Partial Vacuum for Which Tank Was Designed.

Following the tests specified in NC-6524 or in NC-6525, the pressure in the tank shall be released and a manometer shall be connected to the vapor space. The ability of that part of the tank to withstand the partial vacuum for which it is designed shall then be checked by withdrawing water from the tank or by air evacuation, with all vents closed, until the design partial vacuum is developed. Careful observations shall be made under the above condition of loading to determine whether any appreciable changes occur in the shape of the tank.

NC-6530 TEST GAGES

NC-6531 Indicating Gage and Its Location

An indicating gage shall be connected directly to the topmost part of the roof on the tank under test, except that, in the case of a tank which is designed for storage of gases or vapors alone and is to be tested only with air, this gage may be connected to the tank at some lower level. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator throughout the duration of the test. Means shall be provided so that the required test pressure will not be exceeded.

NC-6532 Recording Gage and Its Location

A recording gage shall also be used on each tank, and a record shall be kept of the pressures during all stages of the tests. This gage shall be connected either to the piping leading to the indicating gage or directly to the tank at a point near the indicating gage connection.

NC-6533 Accumulation of Static Head on Gages

In all cases in which a gage is mounted at a level lower than its connection to the tank or lower than some part of the piping leading to the gage, suitable precautions shall be taken to prevent accumulation of any static head of condensed moisture or water from other sources in the piping leads above the level of the gage.

NC-6534 Calibration of Pressure Test Gages

All test gages shall be calibrated against a standard dead weight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests, using the same pressure test gage or gages, which are conducted within a period not exceeding two weeks.

NC-6600 SPECIAL TEST PRESSURE SITUATIONS

NC-6610 COMPONENTS DESIGNED FOR EXTERNAL PRESSURE

Components designed for external pressure only shall be subjected to an internal test pressure at 1.25 times the design external pressure. The pressure shall be

Page 310

under proper control so that the required test pressure is never exceeded by more than 6%.

NC-6620 PRESSURE TESTING OF COMBINATION UNITS

NC-6621 Pressure Chambers Designed to Operate Independently

Pressure chambers of combination units that have been designed to operate independently shall be pressure tested as separate vessels, that is, each chamber shall be tested without pressure in the adjacent chamber.

NC-6622 Common Elements Designed for a Maximum Differential Pressure

(a) When pressure chambers of combination units have their common elements designed for the maximum differential pressure that can occur during startup, operation, and shutdown, and the differential pressure is less than the higher of the Design Pressures of the adjacent chambers, the common elements shall be subjected to a pressure test of at least 1.25 times the maximum differential pressure.

(b) Following the test of the common elements, as required by NC-6622(a) and their inspection, the adjacent chambers shall be pressure tested (NC-6221). Care must be taken to limit the differential pressure between the chambers to the pressure used when testing the common elements.

NC-6900 PROOF TESTS TO ESTABLISH DESIGN PRESSURE

NC-6910 GENERAL REQUIREMENTS

NC-6911 Establishment by Test of Design Pressure

The Design Pressure for components, except those designed to NC-3200, and piping or component parts for which the strength cannot be computed with a satisfactory assurance of accuracy, shall be established in accordance with the requirements of this Subarticle, using one of the test procedures applicable to the type of loading and to the material used in construction.

NC-6911.1 Types of Proof Tests.

Provision is made in these rules for two types of tests to determine the internal Design Pressure:

(a) tests based on yielding of the part to be tested (these tests are limited to materials with a ratio of specified minimum yield to specified minimum ultimate strength of 0.625 or less);

(b) tests based on bursting of the part.

NC-6911.2 Purpose for Which Proof Tests May Be Used.

The tests in this Subarticle may be used only for the purpose of establishing the Design Pressure of those elements or component parts for which the thickness cannot be determined by means of the design rules given in this Subsection. The Design Pressure of all other elements or component parts shall not be greater than that determined by means of the applicable design rules.

NC-6911.3 Permissible Previous Pressurization of Component or Part.

The component or component part for which the Design Pressure is to be established shall not previously have been subjected to a pressure greater than $1\frac{1}{2}$ times the desired or anticipated Design Pressure, adjusted for Design Temperature as provided in NC-6911.9.

NC-6911.4 Test Requirements for Duplicate Components or Parts.

When the Design Pressure of a component or component part has been established by a proof test, duplicate parts of the same materials, design, and construction need not be proof tested but shall be given a hydrostatic test in accordance with NC-6200 or a pneumatic test in accordance with NC-6300. The dimensions and minimum thickness of the structure to be tested shall not vary materially from those actually used. A geometrically similar part may be qualified by a series of tests covering the complete size range of the pressure part.

NC-6911.5 Application of Pressure.

In the procedures given in NC-6921, NC-6923, and NC-6924, the hydrostatic pressure in the component or component

part shall be increased gradually until approximately one-half the anticipated Design Pressure is reached. Thereafter, the test pressure shall be increased in steps of approximately one-tenth or less of the anticipated Design Pressure until the pressure required by the test procedure is reached. The pressure shall be held stationary at the end of each increment for a sufficient time to allow the observations required by the test procedure to be made and shall be released to zero to permit determination of any permanent strain after any pressure increment that indicates an increase in strain or displacement over the previous equal pressure increment.

NC-6911.6 Check of Measurements.

As a check that the measurements are being taken on the most critical areas, the Inspector may require a lime wash

Page 311

or other brittle coating to be applied on all areas of probable high stress concentrations in the test procedures given in NC-6923 and NC-6924. The surfaces shall be suitably cleaned before the coating is applied in order to obtain satisfactory adhesion. The technique shall be suited to the coating material.

NC-6911.7 Determination of Design Pressure for Components or Parts Having Corrosion Allowance.

The test procedures in this Subarticle give the Design Pressure for the thickness of material tested. When the thickness as tested includes extra thickness as provided in NC-3121, the Design Pressure at which the component shall be permitted to operate shall be determined by multiplying the Design Pressure obtained from the test by the ratio

$$(t - c)/t$$

where

t = nominal thickness of the material at the weakest point, in.

c = allowance added for corrosion, erosion, and abrasion, in.

NC-6911.8 Determination of Yield Strength and Tensile Strength

(a) For proof tests based on yielding (NC-6921, NC-6923, or NC-6924), the yield strength (or yield point, for those materials which exhibit that type of yield behavior indicated by a "sharp-kneed" portion of the stress-strain diagram) of the material in the part tested shall be determined in accordance with the method prescribed in the applicable material specification and as described in ASTM E 8-1972. For proof tests based on bursting, NC-6922, the tensile strength instead of the yield strength of the material in the part tested shall be similarly determined.
